Uremia affects the entire GI system. The normal flora of the mouth changes with uremia. The mouth contains the enzyme *urease*, which breaks down urea into ammonia. The ammonia generated from this reaction causes **halitosis** (bad breath) and may also cause **stomatitis** (mouth inflammation).

Anorexia, nausea, vomiting, and hiccups are common in patients with uremia. The specific cause of these problems is unknown but may be related to high BUN and creatinine levels as well as acidosis.

Peptic ulcer disease is common in patients with uremia, but the exact cause is unclear. Uremic colitis with watery diarrhea or constipation may also be present with uremia. Ulcers may occur in the stomach or small or large intestine, causing erosion of blood vessels. The blood loss caused by these erosions may lead to hemorrhagic shock from severe GI bleeding.

Etiology and Genetic Risk

The causes of CKD are complex (Table 71-7). More than 100 different disease processes can result in progressive loss of kidney function (see also Chapter 70). Two main causes of ESKD are hypertension and diabetes mellitus (USRDS, 2010). Infection and genetic kidney diseases also can lead to ESKD (Nussbaum et al., 2007). African-American patients are four times more likely to develop ESKD and seven times more likely to have hypertensive ESKD.

Incidence/Prevalence

The number of patients being treated for CKD is increasing. The 2010 U.S. Renal Data Systems' annual report stated that 527,283 people in the United States were under treatment for ESKD. In 2007, the reported incidence of kidney disease (new patients per year requiring renal replacement therapy)

TABLE 71-7 SELECTED CAUSES OF CHRONIC KIDNEY DISEASE

Glomerular Disease - Glomerulonephritis - Basement membrane disease - Goodpasture's syndrome - Inter-capillary glomerulosclerosis	Infection - Pyelonephritis - Tuberculosis
Tubular Disease - Chronic hypercalcemia - Chronic potassium depletion - Fanconi's syndrome - Heavy metal (lead) poisoning	Systemic Vascular Disease - Intrarenal renovascular hypertension - Extrarenal renovascular hypertension
Vascular Disease of the Kidney - Ischemic disease of the kidney - Bilateral renal artery stenosis - Nephrosclerosis - Hyperparathyroidism	Metabolic Kidney Disease - Amyloidosis - Gout (hyperuricemic nephropathy) - Diabetic nephropathy - Milk-alkali syndrome - Sarcoidosis
Urinary Tract Disease Obstructive uropathy	Connective Tissue Disease - Progressive systemic sclerosis - Systemic lupus erythematosus - Polyarteritis
Inherited or Genetic Conditions - Hypoplastic kidneys - Medullary cystic disease - Polycystic kidney disease	

NOTE: List is not all-inclusive.

was close to 110,000. More than 24% of patients with ESKD die during the first year of treatment. ESKD occurs more often in men than in women (USRDS, 2010). The greatest increase in ESKD is in patients 65 years of age and older. **Chart 71-5** addresses prevention of kidney and urinary problems.

Health Promotion and Maintenance

The health-promotion activities to prevent or delay the onset of CKD focus on controlling the diseases that lead to its development, such as diabetes and hypertension. Identifying patients who have these disorders at an early stage is critical to CKD prevention. Teach patients to adhere to drug and diet regimens and engage in regular physical activity to prevent the blood vessel changes that lead to kidney damage. Instruct patients with diabetes to keep their blood glucose levels within the prescribed range. Teach patients with hypertension that drug therapy is not a cure and must be continued along with lifestyle changes. Urge patients with diabetes or hypertension to have yearly testing for microalbuminuria.

Teach everyone treated for an infection anywhere in the kidney/urinary system to take all antibiotics as prescribed. Urge everyone to drink at least 3 L of water daily unless a health problem requires fluid restriction. Caution people who use over-the-counter NSAIDs to avoid abusing these drugs because they reduce blood flow to the kidney and their long-term use reduces kidney function (Solomon, 2010). **Chart 71-5** is a patient education guide for prevention of kidney and urinary problems.

CHART 71-5 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Prevention of Kidney and Urinary Problems

- Be alert to the general appearance of your urine. Note any changes in its color, clarity, or odor.
- Changes in the frequency or volume of urine passage occur with changes in fluid intake. More frequent or infrequent voiding not associated with changes in fluid intake may signal potential problems.
- Any discomfort or distress with the passage of urine is not normal. Pain, burning, urgency, aching, or difficulty with initiating urine flow or complete bladder emptying is of some concern.
- The kidneys need 1 to 2 quarts of fluid a day to flush out your body wastes. Water is the ideal flushing agent.
- Reduce your intake of carbonated soft drinks.
- Changes in kidney function are often silent for many years. Periodically ask your health care provider to measure your kidney function with a blood test (serum creatinine) and a urinalysis.
- If you have a history of kidney disease, diabetes mellitus, hypertension (high blood pressure), or a family history of kidney disease, you should know your serum creatinine level and your 24-hour creatinine clearance. At least one checkup per year that includes laboratory blood and urine testing of kidney function is recommended.
- If you are identified as having decreased kidney function, ask about whether any prescribed drug, diet, diagnostic test, or therapeutic procedure will present a risk to your current kidney function. Check out all nonprescription drugs with your physician or pharmacist before using them.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

History

When taking a history from a patient with suspected chronic kidney disease (CKD), document the patient's age and gender. Accurately measure weight and height, and ask about usual weight and recent weight gain or loss. Weight gain may indicate fluid retention from poor kidney function. Weight loss may be the result of anorexia from high blood urea levels.

Obtain a complete history of known kidney or urologic disorders, long-term health problems, drug use, and current health problems. Ask the patient about any existing kidney disease or family history of kidney disease that might indicate a genetic problem. A history of kidney infection or stones may imply past kidney damage. Explore the possibility of long-term health problems, because illnesses such as hypertension, diabetes, systemic lupus erythematosus, arthritis, cancer, and tuberculosis can cause decreased kidney function.

Document the use of current and past prescription and over-the-counter drugs, because many drugs are nephrotoxic and can cause kidney damage (see **Table 71-5**).

Examine the patient's dietary habits, and discuss any present GI problems. A change in the taste of foods often occurs with CKD. Patients may report that sweet foods are not as appealing or that meats have a metallic taste. Ask about the presence of nausea, vomiting, anorexia, hiccups, diarrhea, or constipation. These manifestations may be the result of

excess wastes that the body cannot excrete because of kidney disease.

Ask about the patient's energy level and any recent injuries or bleeding. Explore changes in his or her daily routine as a possible *result* of fatigue. Weakness, drowsiness, and shortness of breath suggest impending pulmonary edema or neurologic degeneration. Ask about bruising or bleeding, which can be caused by hematologic changes from uremia.

Discuss urine elimination in detail, including frequency of urination, appearance of the urine, and any difficulty starting or controlling urination. These data can help identify urologic problems that may influence existing kidney function.

NCLEX EXAMINATION CHALLENGE

Health Promotion and Maintenance

A 40-year-old African-American woman is newly diagnosed with mild chronic kidney disease (CKD). She is otherwise very fit and healthy, and no one in her family has CKD. She asks the nurse whether any of the following factors could have caused this problem. Which factor should the nurse indicate may have influenced the development of CKD?

- She has followed a vegetarian diet that includes eggs but no dairy products for the past 3 years.
- She has taken 220 mg of naproxen twice daily for 3 years.
- Her mother and older sister have type 2 diabetes.
- She drinks 3 liters of water daily.

Physical Assessment/Clinical Manifestations

CKD causes changes in all body systems (Chart 71-6). Most manifestations are related to changes in fluid volume, electrolyte and acid-base imbalances, and buildup of nitrogenous wastes.

Neurologic manifestations of CKD and uremic syndrome vary (see Chart 71-6). Observe for problems ranging from lethargy to seizures or coma, which indicate uremic encephalopathy. Assess for sensory changes that appear in a glove and stocking pattern over the hands and feet. Check for weakness in the upper or lower extremities (e.g., uremic neuropathy).

If untreated, encephalopathy can lead to seizures and coma. Dialysis is used for CKD when neurologic problems result. The manifestations of encephalopathy resolve with dialysis. However, improvement in neuropathy is limited if it is severe and motor function is impaired.

Cardiovascular manifestations of CKD and uremia result from fluid overload, hypertension, heart failure (HF), pericarditis, and potassium-induced dysrhythmias. Assess for signs of reduced sodium and water excretion. Circulatory overload, if untreated, leads to HF, pulmonary edema, peripheral edema, and hypertension.

Assess heart rate and rhythm, listening for extra sounds (particularly an S_3), irregular patterns, or a pericardial friction rub. Unless a hemodialysis (HD) vascular access has been created, measure blood pressure in each arm. Assess the jugular veins for distention, and assess for edema of the feet, shins, and sacrum and around the eyes. Shortness of breath with exertion and at night suggests fluid overload.

Respiratory manifestations of CKD also vary (e.g., breath that smells like urine [*uremic fetor* or uremic halitosis], deep sighing, yawning, shortness of breath). Observe the rhythm, rate, and depth of breathing. **Tachypnea** (increased rate of

CHART 71-6 KEY FEATURES

Severe Chronic Kidney Disease

Neurologic Manifestations

- Lethargy and daytime drowsiness
- Inability to concentrate or decreased attention span
- Seizures
- Coma
- Slurred speech
- Asterixis (jerky movements or "flapping" of the hands)
- Tremors, twitching, or jerky movements
- Myoclonus
- Ataxia (alteration in gait)
- Paresthesias

Cardiovascular Manifestations

- Cardiomyopathy
- Hypertension
- Peripheral edema
- Heart failure
- Uremic pericarditis
- Pericardial effusion
- Pericardial friction rub
- Cardiac tamponade

Respiratory Manifestations

- Uremic halitosis
- Tachypnea
- Deep sighing, yawning
- Kussmaul respirations
- Uremic pneumonitis
- Shortness of breath
- Pulmonary edema
- Pleural effusion
- Depressed cough reflex
- Crackles

Hematologic Manifestations

- Anemia
- Abnormal bleeding and bruising

Gastrointestinal Manifestations

- Anorexia
- Nausea
- Vomiting
- Metallic taste in the mouth
- Changes in taste acuity and sensation
- Uremic colitis (diarrhea)
- Constipation
- Uremic gastritis (possible GI bleeding)
- Uremic fetor (breath odor)
- Stomatitis

Urinary Manifestations

- Polyuria, nocturia (early)
- Oliguria, anuria (later)
- Proteinuria
- Hematuria
- Diluted, straw-colored appearance (early)
- Concentrated and cloudy appearance (later)

Integumentary Manifestations

- Decreased skin turgor
- Yellow-gray pallor
- Dry skin
- Pruritus
- Ecchymosis
- Purpura
- Soft-tissue calcifications
- Uremic frost (late, preterminal)

Musculoskeletal Manifestations

- Muscle weakness and cramping
- Bone pain
- Pathologic fractures
- Renal osteodystrophy

Reproductive Manifestations

- Decreased fertility
- Infrequent or absent menses
- Decreased libido
- Impotence

breathing) and **hyperpnea** (increased depth of breathing) occur with metabolic acidosis.

With severe metabolic acidosis, extreme increases in rate and depth of ventilation (Kussmaul respirations) occur. A few patients have pneumonitis, or *uremic lung*. In these patients, assess for thick sputum, reduced coughing, tachypnea, and fever. A pleural friction rub may be heard with a stethoscope. Patients often have pleuritic pain with breathing. Auscultate the lungs for crackles, which indicate fluid overload (Martchev, 2008).

Hematologic manifestations of CKD include anemia and abnormal bleeding. Check for indicators of anemia (e.g., fatigue, pallor, lethargy, weakness, shortness of breath, dizziness). Check for abnormal bleeding by observing for

bruising, petechiae, purpura, mucous membrane bleeding in the nose or gums, or intestinal bleeding (black, tarry stools [[melena](#)]).

GI manifestations of CKD include foul breath and mouth ulceration or inflammation. Document any abdominal pain, cramping, or vomiting. Test all stools for occult blood.

Skeletal manifestations of CKD are related to osteodystrophy from poor absorption of calcium and continuous bone calcium resorption. Adults with osteodystrophy have thin, fragile bones that are at risk for pathologic fractures. These bones break easily with even slight trauma. Vertebrae become more compact and may bend forward, leading to an overall loss of height. Ask about changes in height and any unexplained bone pain. Observe for spinal curvatures and any unusual bumps or protrusions in bone areas that may indicate old fractures. Handle the patient carefully during examination and care.

Urine manifestations in CKD failure reflect the kidneys' decreasing function. At first, the amount, frequency, and appearance of the urine change. Protein or blood may be in the urine.

The amount and composition of the urine change as kidney function decreases. With the onset of mild to moderate CKD, the urine may be more dilute and clearer because tubular reabsorption of water is reduced. The actual urine output in a patient with CKD varies with the amount of remaining kidney function. The patient with severe CKD or ESKD usually has oliguria, but some patients continue to produce 1 L or more per 24 hours. Daily urine volume usually changes again after dialysis is started.

Skin manifestations of CKD occur as a result of uremia. Pigment is deposited in the skin, causing a yellowish coloration. Some African Americans report a darkening of the skin. The anemia of CKD causes a sallowness, appearing as a faded sultan on lighter-skinned patients.

Skin oils and turgor are decreased in patients with uremia. A distressing problem of uremia is severe *pruritus* (itching). **Uremic frost**, a layer of urea crystals from evaporated sweat, may appear on the face, eyebrows, axilla, and groin in patients with advanced uremic syndrome. Assess for bruises (*ecchymoses*), purple patches (*purpura*), and rashes.

Psychosocial Assessment

Chronic kidney disease (CKD) and its treatment disrupt many aspects of a patient's life. You are in a unique position to evaluate the patient with newly diagnosed kidney failure and to assist with adjustments.

Psychosocial assessment and support are part of the nurse's role from the time that CKD is first diagnosed. Ask about the patient's understanding of the diagnosis and what the treatment regimen means to him or her (e.g., diet, drugs, dialysis). Assess for anxiety and for the coping styles used by the patient or family members. Psychosocial issues affected by CKD include family relations, social activity, work patterns, body image, and sexual activity. The long-term nature of severe CKD and ESKD, the many treatment options, and the uncertainties about the course of the disease and its treatment require ongoing psychosocial assessment.

Laboratory Assessment

CKD causes extreme changes in many laboratory values (see [Chart 71-2](#)). Monitor the following blood values: creatinine, blood urea nitrogen (BUN), sodium, potassium, calcium,

phosphate, bicarbonate, hemoglobin, and hematocrit. Also monitor GFR for trends.

A urinalysis is performed. In the early stages of CKD, urinalysis may show excessive protein, glucose, red blood cells (RBCs), white blood cells (WBCs), and decreased or fixed specific gravity. Urine osmolarity is usually decreased. Glomerular filtration rate (GFR) is calculated based on serum creatinine levels, age, gender, race, and body size. A 24-hour creatinine clearance also may be calculated after blood and urine creatinine levels are collected and quantified. As CKD progresses, the urine output decreases dramatically.

In severe CKD, measurements of the serum creatinine and BUN levels may be used to determine the presence and degree of uremia. Serum creatinine levels may increase gradually over a period of years, reaching levels of 15 to 30 mg/dL or more, depending on the patient's muscle mass. BUN levels are directly related to dietary protein intake. Without protein restriction, BUN levels may rise 10 to 20 times the value of the serum creatinine level. With dietary protein restriction, BUN levels are elevated but less than those of non-protein-restricted patients. Fluid balance also affects BUN. [Chapter 68](#) describes the significance of BUN and creatinine levels, as well as creatinine clearance.

Imaging Assessment

Few x-ray findings are abnormal with CKD. Bone x-rays of the hand can show renal osteodystrophy. With long-term end-stage kidney disease (ESKD), the kidneys have shrunk (except for ESKD caused by polycystic kidney disease) and may be 8 to 9 cm or smaller. This small size results from atrophy and fibrosis. If CKD progresses suddenly, a kidney ultrasound or CT scan without contrast medium may be used to rule out an obstruction. (See [Chapter 68](#) for a complete description of diagnostic tests for kidney function.)

ANALYSIS

The patient with CKD has usually had a progressive reduction of kidney function and is often hospitalized for adjustment of the treatment plan. The focus of care is to manage symptoms and prevent complications. Priority problems for patients with CKD are:

1. Fluid overload related to the inability of diseased kidneys to maintain body fluid balance
2. Potential for pulmonary edema related to fluid overload
3. Decreased Cardiac Output related to reduced stroke volume, dysrhythmias, fluid overload, and increased peripheral vascular resistance
4. Inadequate nutrition related to inability to ingest, digest food, or absorb nutrients as a result of physiologic factors
5. Potential for infection related to skin breakdown, chronic disease, or malnutrition
6. Potential for injury related to effects of kidney disease on bone density, blood clotting, and drug elimination
7. Fatigue related to kidney disease, anemia, and reduced energy production
8. Anxiety related to threat to or change in health status, economic status, relationships, role function, systems, or self-concept; situational crisis; threat of death; lack of knowledge about diagnostic tests, disease process, treatment; loss of control; or disrupted family life

CHART 71-7 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE**Managing Fluid Volume**

- Weigh the patient daily at the same time each day, using the same scale, with the patient wearing the same amount and type of clothing, and graph the results.
- Observe the weight graph for trends (1 liter of water weighs 1 kilogram).
- Accurately measure all fluid intake and output.
- Teach the patient and family about the need to keep fluid intake within prescribed restricted amounts and to ensure that the prescribed daily amount is evenly distributed throughout the 24 hours.
- Monitor for these manifestations of fluid overload at least every 4 hours:
 - Decreased urine output
 - Rapid, bounding pulse
 - Rapid, shallow respirations
 - Presence of dependent edema
 - Auscultation of crackles or wheezes
 - Presence of distended neck veins in a sitting position
 - Decreased oxygen saturation
 - Elevated blood pressure
 - Narrowed pulse pressure
- Assess level of consciousness and degree of cognition.
- Ask about the presence of headache or blurred vision.

PLANNING AND IMPLEMENTATION

The Concept Map on p. 1554 discusses nursing care issues related to patients who have end-stage kidney disease (ESKD).

Managing Fluid Volume

Planning: Expected Outcomes. The patient with CKD is expected to achieve and maintain an acceptable fluid balance. Indicators include that the blood pressure, body weight, central venous pressure, and serum electrolytes are normal or nearly normal.

Interventions. Management of the patient with CKD includes drug therapy, nutrition therapy, fluid restriction, and dialysis. Nutrition therapy is discussed in the [Enhancing Nutrition](#) section, pp. 1555-1556, and dialysis is discussed in the [Renal Replacement Therapies](#) section, pp. 1558-1567).

The purpose of fluid management is to attain fluid balance and prevent complications of fluid overload ([Chart 71-7](#)). Monitor the patient's intake and output and hydration status. Assess for manifestations of fluid overload (e.g., crackles in the bases of the lungs, edema, and distended neck veins).

Drug therapy with diuretics is prescribed for patients with some kidney impairment to manage fluid retention or help control blood pressure. The increased urine output produced from these drugs helps reduce fluid overload in patients who still have some urine output. Diuretics are seldom used in ESKD after dialysis is started because, as kidney function is reduced, these drugs can have harmful side effects on the remaining kidney cells and on a patient's hearing.

Assess fluid status by obtaining daily weights and reviewing intake and output. Daily weight gain in these patients indicates fluid retention rather than true body weight gain. Estimate the amount of fluid retained: 1 kg of weight equals about 1 L of fluid retained. Weigh the patient daily at the same time each day, on the same scale, wearing the same amount of clothing, and after voiding (if the patient is not

anuric). Monitor weight for changes before and after dialysis.

Fluid restriction is often needed. The amount of fluid restricted is reviewed in the discussion of sodium restriction on p. 1556. Consider all forms of fluid intake, including oral, IV, and fluid or drugs given through gastric tubes, when calculating fluid intake. Assist the patient in spreading oral fluid intake over a 24-hour period. Monitor his or her response to fluid restriction, and notify the health care provider if manifestations of fluid overload persist or worsen.

Preventing Pulmonary Edema

Planning: Expected Outcomes. The patient with CKD is expected to remain free of pulmonary edema by maintaining optimal fluid balance. Indicators include that the patient will have no breathing difficulty, no adventitious lung sounds (e.g., crackles, wheezes) are present on auscultation, and oxygen saturation remains within the patient's usual range.

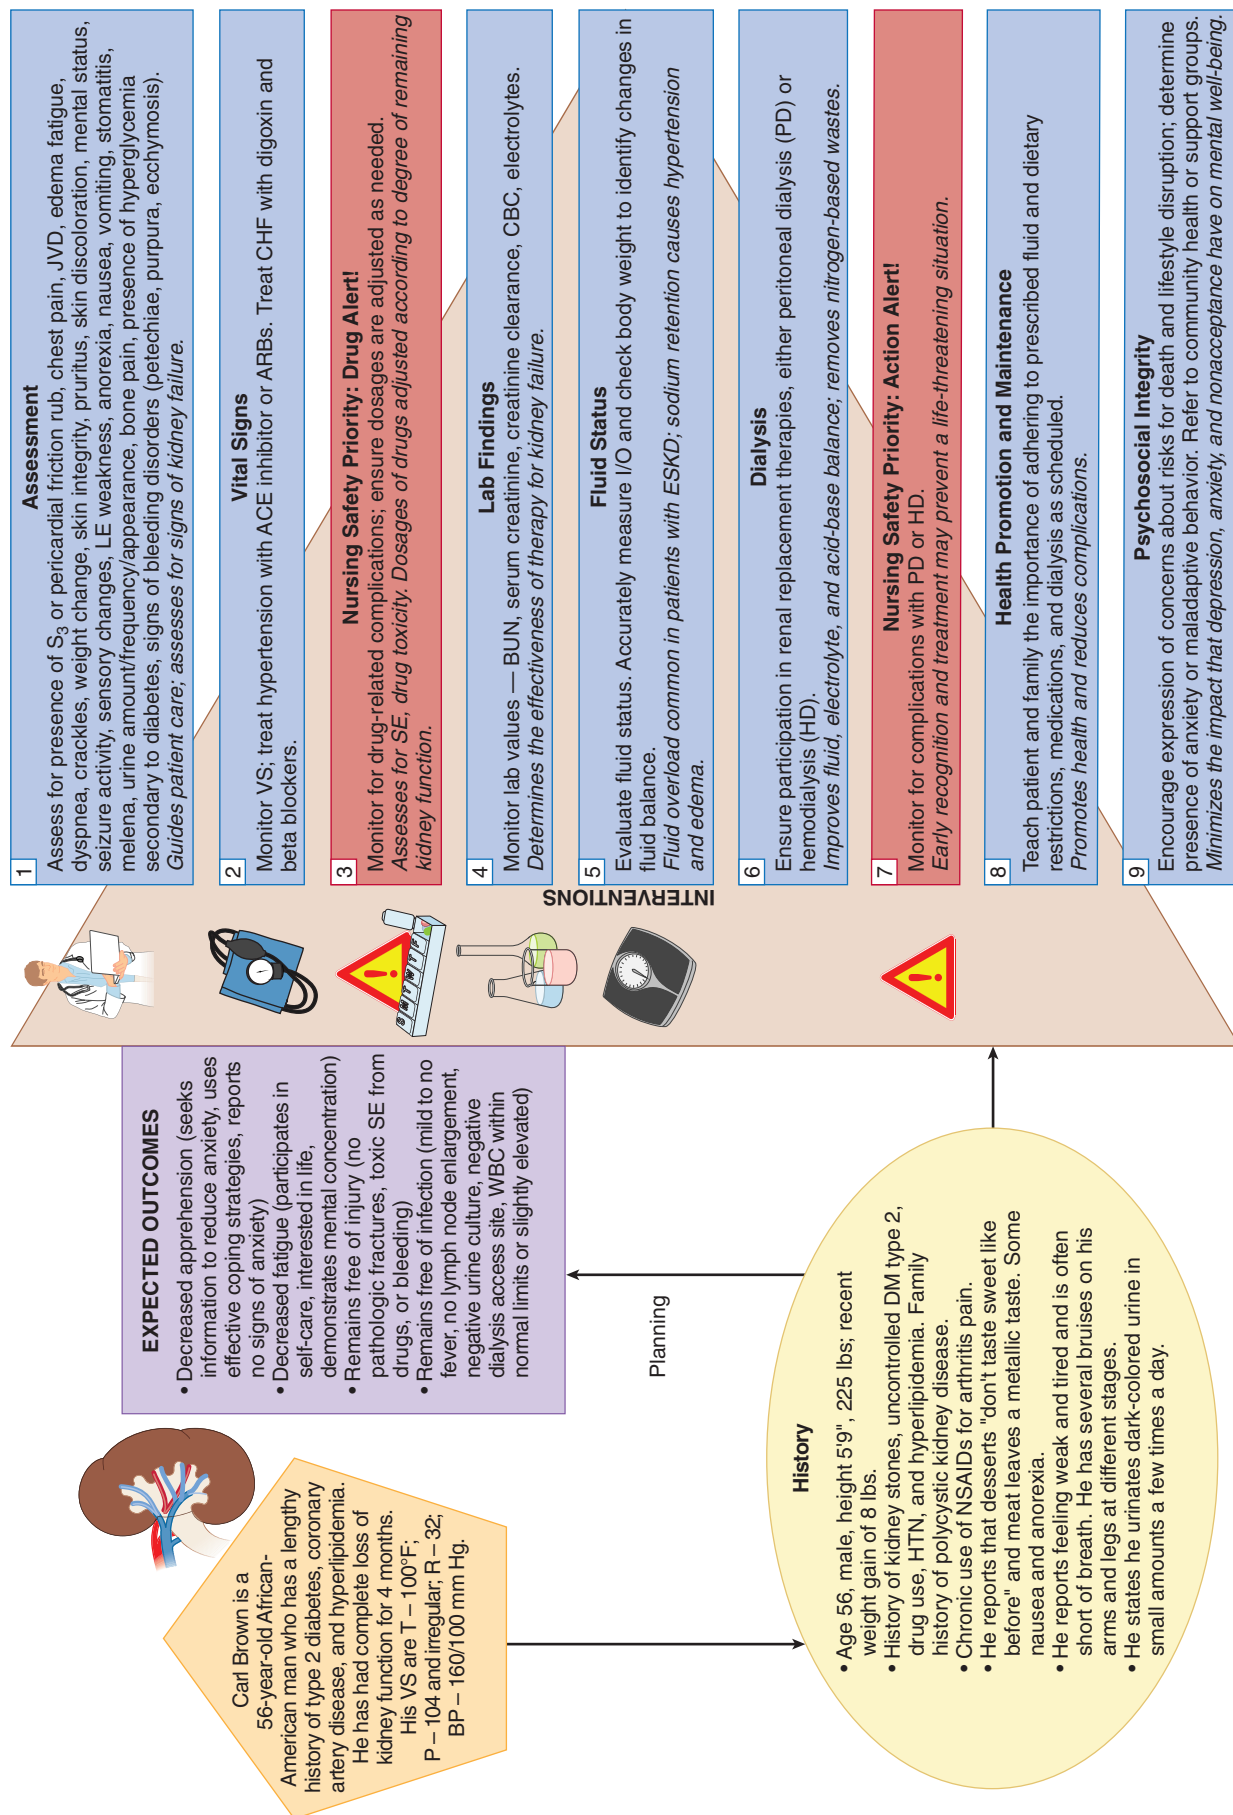

Interventions. In the patient with CKD, pulmonary edema can result from left-sided heart failure related to fluid overload or from blood vessel injury. In left-sided heart failure, the heart is unable to eject blood adequately from the left ventricle, leading to an increased pressure in the left atrium and in the pulmonary blood vessels. The increased pressure causes fluid to cross the capillaries into the pulmonary tissue, forming edema. Pulmonary edema can also occur from injury to the lung blood vessels as a result of uremia. This condition causes inflammation and capillary leak. Fluid then leaks from pulmonary circulation into the lung tissue and the alveoli.

Assess the patient for early signs of pulmonary edema, such as restlessness, anxiety, rapid heart rate, shortness of breath, and crackles that begin at the base of the lungs. As pulmonary edema worsens, the level of fluid in the lungs rises. Auscultation reveals increased crackles and decreased gas exchange. The patient may have frothy, blood-tinged sputum. As cardiac and pulmonary function decrease further, the patient becomes diaphoretic and cyanotic.

The patient with pulmonary edema usually is admitted to the ICU for aggressive treatment and continuous cardiac monitoring. Place the patient in a high-Fowler's position, and give oxygen to improve gas exchange. Drug therapy with kidney failure and pulmonary edema is difficult because of potential adverse drug effects on the kidneys. Treatment of pulmonary edema involves giving loop diuretics, such as furosemide (Lasix), IV. Kidney impairment increases the risk for *ototoxicity* (ear damage with hearing loss) with the use of furosemide; thus IV doses are given cautiously. Diuresis usually begins within 5 minutes of giving IV furosemide. Measure urine output every 15 to 30 minutes during the acute episode and every hour thereafter until the patient is stabilized. Monitor vital signs and assess breath sounds at least every 2 hours to evaluate the patient's response to this treatment.

IV morphine sulfate (1 to 2 mg) is often prescribed to reduce myocardial oxygen demand by triggering blood vessel dilation and to provide sedation. Dosage adjustments are needed to achieve the desired response and avoid respiratory depression. Monitor the patient's respiratory rate, oxygen saturation, and blood pressure hourly during this therapy. Other drugs that dilate blood vessels, such as nitroglycerin, also may be given as a continuous infusion to reduce

Concept Map: End-Stage Kidney Disease

Concept Map by Deanne A. Blach, MSN, RN

pulmonary pressure. Monitor vital signs at least hourly because this drug combination may cause severe hypotension.

Monitor serum electrolyte levels daily, and report abnormalities to the health care provider so that imbalances can be corrected quickly. Monitor ECG tracings at least every 2 hours to identify any dysrhythmias. Monitor oxygen saturation levels by pulse oximetry and arterial blood gas values. Adjust oxygen delivery to maintain adequate oxygen saturation levels. Monitor the patient for worsening of the condition, manifested as increasing hypoxemia. He or she may require temporary intubation and mechanical ventilation to prevent death.

Patients with CKD who have existing cardiac problems, high blood pressure, or chronic fluid retention are at increased risk for developing pulmonary edema. They are less likely to respond quickly to treatment and are more likely to develop problems related to drug therapy. Ultrafiltration may be used with these patients to reduce fluid volume.

NCLEX EXAMINATION CHALLENGE

Safe and Effective Care Environment

The client with end-stage kidney disease (ESKD) appears to have pulmonary edema. Which intervention does the nurse perform first?

- A. Raise the head of the bed
- B. Apply oxygen by nasal cannula
- C. Notify the Rapid Response Team
- D. Measure oxygen saturation by pulse oximetry

Increasing Cardiac Output

Planning: Expected Outcomes. The patient with CKD is expected to attain and maintain adequate cardiac output. Indicators include that systolic and diastolic blood pressures, ejection fraction, peripheral pulses, and cognitive status are either normal or nearly normal.

Interventions. Many patients with long-standing hypertension are at risk for kidney disease and have mild CKD. Some progress to severe CKD and ESKD. *Therefore blood pressure control is essential in preserving kidney function.* To control blood pressure, calcium channel blockers, angiotensin-converting enzyme (ACE) inhibitors, alpha-adrenergic and beta-adrenergic blockers, and vasodilators may be prescribed. ACE inhibitors appear to be the most effective drugs to slow the progression of kidney failure. Calcium channel blockers seem to improve the GFR and blood flow within the kidney.

More information on the specific drugs for blood pressure control can be found in [Chapter 38](#). Indications vary depending on the patient, and these drugs are used carefully to avoid complications. Different combinations and doses may be tried until blood pressure control is adequate and side effects are minimized.

Teach the patient and family to measure blood pressure daily. Evaluate their ability to measure and record blood pressure accurately using their own equipment. Re-check measurement accuracy on a regular basis. The patient and family must understand the relationship of blood pressure control to diet and drug therapy. Also instruct the patient to weigh daily and to bring records of blood pressure measurements, drug administration times, and weights for discussion with the physician, nurse, or dietitian.

Assess the patient on an ongoing basis for manifestations of reduced cardiac output, heart failure, and dysrhythmias. These topics are discussed in [Chapters 36 through 38](#).

Enhancing Nutrition

Planning: Expected Outcomes. The patient with CKD is expected to maintain adequate nutrition. The patient should have a caloric intake appropriate for his or her weight-to-height ratio, muscle tone, and laboratory values (serum albumin, hematocrit, hemoglobin).

Interventions. The nutritional needs and diet restrictions for the patient with CKD vary according to the degree of remaining kidney function and the type of renal replacement therapy used ([Table 71-8](#)).

The purpose of nutrition therapy is to provide the food and fluids needed to prevent malnutrition. Patients starting hemodialysis (HD) have an increase in protein breakdown and a decrease in intake that results in a loss of lean body mass.

The patient is referred to a dietitian for dietary teaching and planning. Work with the dietitian to teach the patient about diet changes that are needed as a result of CKD. Common changes include control of protein intake; fluid intake limitation; restriction of potassium, sodium, and phosphorus intake; taking vitamin and mineral supplements; and eating enough calories to meet metabolic need.

If adequate calories are not supplied, the body will use muscle protein for energy, which leads to a negative nitrogen balance and malnutrition. The dietitian determines the number of calories and types of nutrients required to meet body needs.

Protein restriction early in the course of the disease prevents some of the symptoms of CKD and may preserve

TABLE 71-8 DIETARY RESTRICTIONS FOR THE PATIENT WITH SEVERE KIDNEY DISEASE AND END-STAGE KIDNEY DISEASE

DIETARY COMPONENT	WITH CHRONIC UREMIA	WITH HEMODIALYSIS	WITH PERITONEAL DIALYSIS
Protein	0.55-0.60 g/kg/day	1.0-1.5 g/kg/day	1.2-1.5 g/kg/day
Fluid	Depends on urine output but may be as high as 1500-3000 mL/day	500-700 mL/day plus amount of urine output	Restriction based on fluid weight gain and blood pressure
Potassium	60-70 mEq/day	70 mEq/day	Usually no restriction
Sodium	1-3 g/day	2-4 g/day	Restriction based on fluid weight gain and blood pressure
Phosphorus	700 mg/day	700 mg/day	800 mg/day

kidney function. Protein is restricted on the basis of the degree of kidney impairment (reduced GFR) and the severity of the symptoms. Buildup of waste products from protein breakdown is the main cause of uremia. Although lower protein levels are recommended, protein-calorie malnutrition must be avoided in patients receiving hemodialysis (HD). At least 1.5 g of protein per kilogram of body weight per day may be needed for weight gain and improved nutritional status in patients receiving maintenance HD.

The glomerular filtration rate (GFR) is used as an indicator of kidney function and as a guide to safe levels of protein intake. A patient with a severely reduced GFR who is *not* undergoing dialysis is usually permitted 0.55 to 0.60 g of protein per kilogram of body weight (e.g., 40 g of protein daily for a 150-pound [about 70-kg] adult). If protein is lost in the urine, protein is added to the diet in amounts equal to that lost in the urine. Protein requirements are calculated based on actual body weight (corrected for edema), not ideal body weight.

The patient receiving dialysis needs more protein because some protein is lost through dialysis. While receiving HD, protein requirements are tailored according to the patient's post-dialysis, or "dry," weight. Generally, HD patients are allowed about 1 to 1.5 g of protein/kg/day. Peritoneal dialysis (PD) patients are allowed 1.2 to 1.5 g of protein/kg/day because protein is lost with each exchange. Suggested protein-containing foods are milk, meat, or eggs. If protein intake is not adequate, a negative nitrogen balance develops and causes muscle wasting. BUN and serum prealbumin levels and albumin levels are used to monitor the adequacy of protein intake. Decreased serum prealbumin or albumin levels indicate poor protein intake. Excessive protein intake increases BUN levels in patients with CKD.

Sodium restriction is needed in patients with little or no urine output. Both fluid and sodium retention cause edema, hypertension, and heart failure (HF). Most patients with CKD retain sodium; a few cannot conserve sodium.

Estimate fluid and sodium retention status by monitoring the patient's body weight and blood pressure. In uremic patients not receiving dialysis, sodium is limited to 1 to 3 g daily and fluid intake depends on urine output. In patients receiving dialysis, the sodium restriction is 2 to 4 g daily and fluid intake is limited to 500 to 700 mL plus the amount of any urine output. Instruct the patient not to add salt at the table or during cooking. Foods high in sodium (e.g., processed foods, fast foods, potato chips, pretzels, pickles, ham, bacon, sausage) are permitted in moderation. Herbs and spices can be used in place of salt to enhance food flavor.

Potassium restriction may be needed because high blood potassium levels can cause dangerous cardiac dysrhythmias. Monitor the ECG for tall, peaked T waves caused by hyperkalemia. Document serum potassium levels. Instruct the patient with ESKD to limit potassium intake to 60 to 70 mEq/day. Teach him or her to read labels of seasoning agents carefully for sodium and potassium content. [Chart 13-8](#) in [Chapter 13](#) lists common foods that are low in potassium along with foods that are high in potassium and should be avoided. Instruct patients to avoid salt substitutes composed of potassium chloride. Those receiving PD or who are producing urine may not need potassium restriction.

Phosphorus restriction for control of phosphate levels is started early in CKD to avoid osteodystrophy (bone defects).

Monitor serum phosphate levels. Dietary phosphorus restrictions and drugs to assist with phosphate control may be prescribed. Phosphate binders must be taken at mealtimes. Most patients with CKD already restrict their protein intake, and because high-protein foods are also high in phosphorus, this reduces phosphorus intake. [Chapter 13](#) lists foods high in potassium, sodium, and phosphorus.

Vitamin supplementation is needed daily for most patients with CKD. Low-protein diets are also low in vitamins, and water-soluble vitamins are removed from the blood during dialysis. Anemia also is a problem in patients with CKD because of the limited iron content of low-protein diets and decreased kidney production of erythropoietin. Thus supplemental iron is needed. Calcium and vitamin D supplements may be needed, depending on the patient's serum calcium levels and bone status.

Nutritional needs for patients undergoing PD are slightly different from those undergoing HD. Because protein is lost with the dialysate in PD, replacing lost protein is needed. Often 1.2 to 1.5 g of protein per kilogram of body weight per day is recommended. Patients may have anorexia and have difficulty eating enough protein. High-calorie enteral supplements may also be needed (e.g., Magnacal Renal, Ensure Plus). Sodium restriction varies with fluid weight gain and blood pressure. Usually dietary potassium does not need to be restricted because the dialysate is potassium-free. Any potassium restriction is determined by serum potassium levels.

Collaborate with the dietitian to assess each patient's nutritional needs. Teach the patient and evaluate his or her understanding of and adherence with dietary regimens. Give the patient and family written examples of the diet to promote adherence. Help patients adapt the diet to their budget, ethnic background, and food preferences to meet the diet's restrictions.

Preventing Infection

Planning: Expected Outcomes. The patient with CKD is expected to remain free of infection. Indicators include that the patient will have only mild or no fever, no lymph node enlargement, negative urine culture, negative dialysis access site culture, and white blood cell count either within the normal range or only slightly elevated.

Interventions. Provide meticulous care to any areas where skin is not intact (e.g., AV grafts and fistulas, incisions, site of drains, puncture sites, cracked or excoriated skin, pressure sores), and provide preventive skin care to intact areas. For patients undergoing dialysis, inspect the vascular access site or peritoneal dialysis (PD) catheter insertion site every shift for redness, swelling, pain, and drainage. Monitor vital signs for any manifestation of infection (e.g., fever, tachycardia).

Preventing Injury

Planning: Expected Outcomes. The patient with CKD is expected to remain free of injury. Indicators include that the patient should not have any of the following problems:

- Pathologic fractures
- Toxic side effects from drug therapy
- Bleeding

Interventions. *Injury prevention strategies* are needed because the patient with long-standing CKD may have brittle, fragile bones that fracture easily and cause little pain. When

lifting or moving a patient with fragile bones, use a lift sheet rather than pulling the patient. Teach unlicensed assistive personnel (UAP) the correct use of lift sheets. Observe for normal range of joint motion and for unusual surface bumps or depressions over bones, which may indicate fractures.

Managing drug therapy in patients with CKD is a complex clinical problem. Many over-the-counter drugs contain agents that alter kidney function. Therefore it is important to obtain a detailed drug history. Know the use of each drug, its side effects, and its site of metabolism.

Certain drugs must be avoided, and the dosages of others must be adjusted according to the degree of remaining kidney function. As the patient's kidney function decreases, repeated dosage adjustments are necessary. Assess for side effects and signs of drug toxicity, and notify the prescriber as appropriate.

NURSING SAFETY ALERT

Drug Alert

Monitor the patient with severe CKD or ESKD closely for drug-related complications, and ensure that dosages are adjusted as needed.

Many drugs are routinely given to patients with CKD (see [Chart 71-3](#)). Know the rationale for these drugs and the indicated nursing interventions. Many patients also have cardiac disease and may require cardiac drugs such as digoxin. Patients with severe CKD and ESKD are particularly at risk for digoxin toxicity because the drug is excreted by the kidneys. When caring for patients with CKD who are receiving digoxin, monitor for signs of toxicity, such as nausea, vomiting, anorexia, visual changes, restlessness, headache, fatigue, confusion, *bradycardia* (pulse rate less than 50 to 60 beats/min), and *tachycardia* (pulse rate greater than 100 beats/min). Monitor the serum drug levels to be certain they are in the therapeutic range (0.8-2 ng/mL). Also closely monitor the serum potassium levels of any patient receiving digoxin.

NURSING SAFETY PRIORITY

Drug Alert

Doses of digoxin are generally much lower than for most drugs. When digoxin is administered to older adults with kidney disease, the prescribed dose may be even lower (0.0625-0.125 mg). Check and re-check the dosage before administering digoxin to a patient with kidney disease.

Drugs to control an excessively high phosphate level include phosphate-binding agents. Calcium acetate, calcium carbonate, and aluminum hydroxide are used as phosphate-binding agents in patients with impaired kidney function or CKD. These drugs help prevent renal osteodystrophy and related injuries. Stress the importance of taking these agents and all prescribed drugs.

Hypophosphatemia (low serum phosphorus levels) is a complication of phosphate binding, especially in patients who are not eating adequately but who are continuing to take phosphate-binding drugs. *Hypercalcemia* (high serum calcium levels) also is a possible complication for patients taking calcium-containing compounds to control phosphate excess. In patients taking aluminum-based phosphate binders

for prolonged periods, aluminum deposits may cause bone disease or permanent neurologic problems. Monitor the patient for muscle weakness, anorexia, malaise, tremors, or bone pain.

Teach patients with kidney disease to avoid antacids containing magnesium. These patients cannot excrete magnesium and thus should avoid additional intake.

Some drugs, in addition to those used to manage CKD, require special attention. These drugs include antibiotics, opioids, antihypertensives, diuretics, insulin, and heparin.

Many antibiotics are safe for patients with CKD, but those excreted by the kidney require dose adjustment. To prevent complications of bloodstream infections from mouth bacteria, prophylactic antibiotic treatment is given to patients with CKD before any dental procedures. The antibiotic used varies with the patient's needs and the physician's preference.

Give opioid analgesics cautiously in patients with severe CKD or ESKD because the effects often last longer than in those with healthy kidneys. Patients with uremia are sensitive to the respiratory depressant effects of these drugs. Because opioids are broken down by the liver and not the kidneys, the dosages are often the same regardless of the level of kidney function. Monitor the patient's reactions closely after opioids are given to determine whether adjustments are needed.

As CKD progresses, the patient with diabetes often requires reduced doses of insulin or antidiabetic drugs because the failing kidneys do not excrete or metabolize these drugs well. Thus the drugs are effective longer, increasing the risk for hypoglycemia. Monitor blood glucose levels at least four times per day to determine whether a dosage change is needed.

Poor platelet function and capillary fragility in CKD make anticoagulant therapy risky. Monitor patients receiving heparin, warfarin, or any anticoagulant every shift for bleeding. See [Chapter 42](#) for more information on caring for patients at increased risk for bleeding.

Minimizing Fatigue

Planning: Expected Outcomes. The patient with chronic kidney disease (CKD) is expected to conserve energy by balancing activity and rest. Indicators include that the patient will be able to participate in self-care activities, have interest in surroundings, and demonstrate mental concentration.

Interventions. Some causes of fatigue in the patient with CKD are vitamin deficiency, poor nutrition, anemia, and buildup of urea. All patients are given some type of vitamin and mineral supplement because of diet restrictions and vitamin losses from dialysis. Avoid giving these supplements before hemodialysis (HD) treatment because they will be dialyzed out of the body and the patient will receive no benefit.

The anemic patient with CKD is treated with erythropoietin (Epogen, Procrit). The outcome of this therapy is to maintain a hematocrit of 30% to 35%. This therapy is effective in triggering bone marrow production of red blood cells if the patient has adequate iron stores. Iron supplements may be needed if patients are iron deficient. Many who receive erythropoietin report improved appetite and sexual function along with decreased fatigue. The increased production of all blood cells from this therapy may increase blood pressure. The improved appetite challenges patients in their attempts to maintain protein, potassium, and fluid restrictions and requires additional education.

Reducing Anxiety

Planning: Expected Outcomes. The patient with CKD is expected to have reduced tension and apprehension. Indicators include that the patient consistently demonstrates these behaviors:

- Seeks information to reduce anxiety
- Uses effective coping strategies
- Reports an absence of physical manifestations of anxiety

Interventions. The nurse coordinates a team of health care professionals to support and counsel the patient and family, often over many years of treatment. The nurse has the most contact with the patient with severe CKD and ESKD when the patient is hospitalized or undergoing in-center dialysis treatments. Perform an ongoing assessment of the patient's anxiety level to determine the level of nursing intervention required. Observe his or her behavior for cues indicating anxiety (e.g., anxious facial expressions, clenching of hands, tapping of feet, withdrawn posture, absence of eye contact, an increased pulse rate). Evaluate the support systems, such as the involvement of family and friends with the patient's care.

Unfamiliar settings and lack of knowledge about treatments and tests can increase the patient's anxiety level. Explain all procedures, tests, and treatments. Identify the patient's knowledge needs about kidney function and kidney disease. Provide instruction at a level he or she can understand using a variety of written and visual materials.

Provide continuity of care, whenever possible, by using a consistent nurse-patient relationship to decrease anxiety and promote discussions of concerns. As you develop the nurse-patient relationship, encourage the patient to discuss current problems or concerns.

Encourage the patient to ask questions and discuss fears about the diagnosis of severe kidney disease or ESKD. An open atmosphere that allows for discussion can decrease anxiety. Facilitate discussions with family members about the prognosis and the impact on lifestyle. Assist the patient to identify strategies for maintaining quality of life.

Renal Replacement Therapies

Renal replacement therapy is needed when the pathologic changes of stage 4 and stage 5 chronic kidney disease (CKD) are life threatening or pose continuing discomfort to the patient. When he or she can no longer be managed with conservative therapies, such as diet, drugs, and fluid restriction, dialysis is indicated. Transplantation may be discussed at any time.

Hemodialysis

Hemodialysis (HD) is the most common renal replacement therapy used with ESKD and kidney failure (Table 71-9). Dialysis removes excess fluids and waste products and restores chemical and electrolyte balance. HD involves passing the patient's blood through an artificial semipermeable membrane to perform the filtering and excretion functions of the kidney.

Patient Selection. Any patient may be considered for HD therapy. Starting this therapy depends on symptoms, not on the glomerular filtration rate (GFR). Dialysis is started immediately for patients who have the following: fluid overload that does not respond to diuretics, pericarditis, uncontrolled

TABLE 71-9 A COMPARISON OF HEMODIALYSIS AND PERITONEAL DIALYSIS AS RENAL REPLACEMENT THERAPY OPTIONS

HEMODIALYSIS	PERITONEAL DIALYSIS
Advantages	
More efficient clearance	Easy access
Short time needed for treatment	Few hemodynamic complications
Complications	
Disequilibrium syndrome	Protein loss
Muscle cramps	Peritonitis
Hemorrhage	Hyperglycemia
Air embolus	Respiratory distress
Hemodynamic changes (hypotension, anemia)	Bowel perforation
Cardiac dysrhythmias	Infection
Infection	
Contraindications	
Hemodynamic instability	Extensive peritoneal adhesions
	Peritoneal fibrosis
	Recent abdominal surgery
Access	
Vascular access route	Intra-abdominal catheter
Procedure	
Complex	Simple
Specially trained registered nurses required	Training less complex than for hemodialysis
Nursing Implications	
Vascular access care	Abdominal catheter care
Restrict diet	More flexible diet

hypertension, neurologic problems, and development of bleeding. Most commonly, dialysis is started when uremic manifestations, such as nausea and vomiting, decreased attention span, decreased cognition, worsening anemia, and pruritus, are present.

Many patients survive for years with HD therapy, and others may live only a few months. How long the patient survives using HD therapy depends on his or her age, the cause of kidney failure, and the presence of other diseases, such as coronary artery disease, hypertension, or diabetes. General patient selection criteria are:

- Irreversible kidney failure when other therapies are unacceptable or ineffective
- Absence of illnesses that would seriously complicate HD
- Expectation of rehabilitation
- The patient's acceptance of the regimen

Dialysis Settings. Patients with CKD may receive HD treatments in many settings, depending on specific needs. Regardless of the setting for therapy, they need ongoing nursing support to maintain this complex and lifesaving treatment.

Patients may be dialyzed in a hospital-based center if they have recently started treatment or have complicated conditions that require close supervision. Stable patients not requiring intense supervision may be dialyzed in a community or freestanding HD center. Selected patients may participate in complete or partial self-care in an outpatient center or in in-home HD.

In-home HD is the least disruptive and allows the patient to adapt the regimen to his or her lifestyle. Unfortunately, many cannot participate in in-home dialysis because they lack a skilled partner to assist with the therapy and manage the dialysis machine. Some patients and partners find the use of in-home dialysis to be too stressful. In addition, a water treatment system must be installed in the home to provide a safe, clean water supply for the dialysis process.

Procedure. Dialysis works using the passive transfer of toxins by diffusion. **Diffusion** is the movement of molecules from an area of higher concentration to an area of lower concentration. The rate of diffusion during dialysis occurs more rapidly when the membrane pores are large, there is a large surface area of membrane, the temperature of the solutions is higher, and there is a greater difference in the solute concentrations between the patient's blood and the dialysate. Large molecules, such as RBCs and most plasma proteins, cannot pass through the membrane.

When HD is started, blood and **dialysate** (dialyzing solution) flow in opposite directions across an enclosed semipermeable membrane. The dialysate contains a balanced mix of electrolytes and water that closely resembles human plasma. On the other side of the membrane is the patient's blood, which contains nitrogen waste products, excess water, and excess electrolytes. During HD, the waste products move from the blood into the dialysate because of the difference in their concentrations (diffusion). Excess water is also removed from the blood into the dialysate by *osmosis* (movement of water across a semipermeable membrane from a solution that has a lower osmolarity or concentration to a solution with a higher osmolarity or concentration). Electrolytes can move in either direction, as needed, and take some fluid with them. Potassium and sodium typically move out of the plasma into the dialysate. Bicarbonate and calcium generally move from the dialysate into the plasma. This circulating process continues for a preset length of time, restoring water, electrolyte, and acid-base balance and removing nitrogenous wastes. Water volume may be removed from the plasma by applying positive or negative pressure to the system.

The HD system includes a dialyzer, dialysate, vascular access routes, and an HD machine. The artificial kidney, or **dialyzer** (Fig. 71-3), has four parts: a blood compartment, a dialysate compartment, a semipermeable membrane, and an enclosed support structure.

Dialysate is made from clear water and chemicals and is free of any waste products or drugs. Because bacteria and other organisms are too large to pass through the membrane, dialysate is not sterile. The water used in dialysate must meet specific standards and usually requires special treatment before mixing the dialysate. The dialysate composition may be altered according to the patient's needs for management of electrolyte imbalances. During HD, the dialysate is warmed to 100° F (37.8° C) to increase the diffusion rate and to prevent hypothermia.

The HD machine has alarm systems to monitor for potential problems, including changes in dialysate temperature, air in the blood tubing, a blood leak in the dialysate compartment, changes in the pressure in either compartment, and changes in composition of the blood or dialysate. If any of these problems are detected, an alarm sounds to protect the patient from life-threatening complications.

FIG. 71-3 Artificial kidney (dialyzer) used in hemodialysis.

FIG. 71-4 A hemodialysis circuit.

All models of HD machines function in a manner similar to that shown in Fig. 71-4. Fig. 71-5 shows one type of HD machine. Fig. 71-6 shows a patient receiving HD. The number and length of treatments depend on the amount of wastes and fluid to be removed, the clearance capacity of the dialyzer, and the blood flow rate to and from the machine. Most patients require about 12 hours per week of total dialysis time. This time is usually divided into three 4-hour treatments. For those with some ongoing urine production, two

FIG. 71-5 Hemodialysis machine.

FIG. 71-6 Patient receiving hemodialysis.

5- to 6-hour treatments a week may be adequate. If the patient gains large amounts of fluid weight, a longer treatment time may be needed to remove the fluid without hypotension or severe side effects.

Anticoagulation. To prevent blood clots from forming within the dialyzer or the blood tubing, anticoagulation is needed during HD treatments. Heparin is the most commonly used drug to prevent clots from forming when blood comes in contact with foreign surfaces. Patient response to heparin varies, and the dose is adjusted based on each patient's need. Those receiving erythropoietin may require additional heparin.

Heparin remains active in the body for 4 to 6 hours after dialysis, making the patient at risk for hemorrhage during and immediately after HD treatments. Invasive procedures must be avoided during that time. Monitor him or her closely for any signs of bleeding or hemorrhage. Clotting tendencies can be monitored during HD with a bedside machine (e.g., the Hemochron), by whole-blood clotting times, or by

TABLE 71-10 TYPES OF VASCULAR ACCESS FOR HEMODIALYSIS

ACCESS TYPE	DESCRIPTION	LOCATION	INITIAL USE
Permanent			
AV fistula	An internal anastomosis of an artery to a vein	Forearm	2-4 mo or longer
AV graft	Synthetic vessel tubing tunneled beneath the skin, connecting an artery and a vein	Forearm Upper arm Inner thigh	1-2 wk
Temporary			
Hemodialysis catheter (dual- or triple-lumen)	A specially designed catheter with two or three lumens. Two lumens are for blood outflow and inflow for hemodialysis; a third allows venous access without accessing dialysis lumens	Subclavian, internal jugular, or femoral vein	Immediately after insertion and x-ray confirmation of placement
Subcutaneous device	An internal device with two metallic access ports and two catheters inserted into large central veins	Subclavian	Immediately after insertion

AV, Arteriovenous.

activated partial thromboplastin times (aPTTs) during and after HD. Protamine sulfate is an antidote to heparin and always should be available in the dialysis setting.

Vascular Access. Vascular access is required for hemodialysis (Table 71-10). The procedure requires the easy availability of a large amount of blood flow: at least 250 to 300 mL/min, usually for a period of 3 to 4 hours. Normal venous cannulation does not provide this high rate of blood flow.

Long-term vascular access is internal for most patients having long-term HD (see Table 71-10). The two common choices are an internal arteriovenous (AV) fistula or an AV graft (Fig. 71-7). *AV fistulas* are formed by surgically connecting an artery to a vein. The vessels used most often are the radial or brachial artery and the cephalic vein of the non-dominant arm. Fistulas increase venous blood flow to 250 to 400 mL/min, the amount needed for effective dialysis.

Time is needed after anastomosis for the AV fistula to develop. As the AV fistula “matures,” the increased pressure of the arterial blood flow into the vein causes the vessel walls to thicken. This thickening increases their strength and durability for repeated cannulation. Patients differ in the amount of time needed for the fistula to mature. Some fistulas may not be ready for use for as long as 4 months after the surgery, and a temporary vascular access (AV shunt or HD catheter) is used during this time. Fig. 71-8 shows a mature fistula.

To access a fistula, cannulate it by inserting two needles, one toward the venous blood flow and one toward the arterial blood flow. This procedure allows the HD machine to draw

FIG. 71-7 Options for long-term vascular access for hemodialysis. **A**, A surgically created venous fistula. The increased pressure from the artery forces blood into the vein. This process causes the vein to dilate enough for fistula needles to be placed for hemodialysis. When the vein dilates in this manner, the fistula is said to be “developed” or “mature.” **B**, A surgically placed straight vascular graft in the upper arm. The graft creates a shunt between arterial and venous blood.

the blood out through the arterial needle and return it through the venous needle.

Arteriovenous grafts are used when the AV fistula does not develop or when complications limit its use. The polytetrafluoroethylene (PTFE) graft is a synthetic material

FIG. 71-8 A mature fistula for hemodialysis access.

(GORE-TEX). This type of graft is commonly used for older patients using HD. Fig. 71-7, B, shows a patient's AV graft.

Precautions. Some precautions are needed to ensure the functioning of an internal AV fistula or AV graft. First assess for adequate circulation in the fistula or graft as well as in the lower portion of the arm. Check distal pulses and capillary refill in the arm with the fistula or graft. Then check for a *bruit* (swishing sound) by auscultating over the access site or a *thrill* (vibration) by palpating over it. The fistula changes in appearance over time as it dilates, and skin stretching increases the risk for injury in the area. Chart 71-8 lists best practices for care of the patient with an HD access.

! NURSING SAFETY PRIORITY

Action Alert

Because repeated compression can result in the loss of the vascular access, avoid taking the blood pressure or performing venipunctures in the arm with the vascular access. Do not use AV fistula or graft for delivery of IV fluids.

Complications. Complications can occur with any type of access. The most common problems are thrombosis or stenosis, infection, aneurysm formation, ischemia, and heart failure.

Thrombosis, or clotting of the AV access, is the most frequent complication. Most grafts fail because of high-pressure arterial flow entering the venous system. The muscle layers of the veins react to this increased pressure by thickening. The venous thickening reduces or occludes blood flow. An interventional radiologist can re-open failing grafts with the injection of a thrombolytic drug (e.g., tPA) to dissolve the clot. The clot usually dissolves within minutes, and often a stricture is revealed at the point where the graft and the vein connect. The stricture can be corrected by balloon angioplasty.

CHART 71-8 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Caring for the Patient with an Arteriovenous Fistula or Arteriovenous Graft

- Do not take blood pressure readings using the extremity in which the vascular access is placed.
- Do not perform venipunctures or start an IV line in the extremity in which the vascular access is placed.
- Palpate for thrills and auscultate for bruits every 4 hours while the patient is awake.
- Assess the patient's distal pulses and circulation in the arm with the access.
- Elevate the affected extremity postoperatively.
- Encourage routine range-of-motion exercises.
- Check for bleeding at needle insertion sites.
- Assess for manifestations of infection at needle sites.
- Instruct the patient not to carry heavy objects or anything that compresses the extremity in which the vascular access is placed.
- Instruct the patient not to sleep with his or her body weight on top of the extremity in which the vascular access is placed.

AV, Arteriovenous.

TABLE 71-11 NURSING INTERVENTIONS FOR PREVENTION OF COMPLICATIONS IN HEMODIALYSIS VASCULAR ACCESS

ACCESS TYPE	BLEEDING	INFECTION	CLOTTING
AV fistula or AV graft	Apply pressure to the needle puncture sites.	Ensure adequate site cleaning before cannulation.	Avoid constrictive devices. Rotate needle insertion sites with each hemodialysis treatment. Assess for thrill and bruit.
Hemodialysis catheters (temporary and permanent)	Monitor the access site.	Use aseptic technique.	Place a heparin or heparin/saline dwell solution after hemodialysis treatment. Not used between treatments.

AV, Arteriovenous.

Most infections of the vascular access are caused by *Staphylococcus aureus* introduced during cannulation. Use sterile technique during cannulation to prevent infection (Table 71-11).

Aneurysms can form in the fistula and are caused by repeated needle punctures at the same site. Large aneurysms may cause loss of the fistula's function and require surgical repair.

Ischemia occurs in a few patients with vascular access when the fistula decreases arterial blood flow to areas below the fistula. Ischemic symptoms ("steal syndrome") vary from cold or numb fingers to gangrene. If the collateral circulation is inadequate, the fistula may need to be surgically tied off and a new one created in another area to preserve extremity circulation.

Shunting of blood directly from the arterial system to the venous system, through the fistula, can cause heart failure in

FIG. 71-9 Temporary jugular hemodialysis access.

patients with limited cardiac function. This complication is rare, but if it does occur, the fistula may need to be revised to reduce arterial blood flow.

Temporary Vascular Access. Temporary access with special catheters has replaced the use of the AV shunt for patients requiring immediate HD. A catheter designed for HD may be inserted into the subclavian, internal jugular, or femoral vein. The lumens of these devices are much smaller than the permanent accesses, and more time (4 to 8 hours) is required to complete each dialysis session.

Devices with subcutaneous access may also be surgically inserted to provide temporary access for HD. Implanted beneath the skin, these devices are composed of two small metallic ports with attached catheters that are inserted into large central veins (Fig. 71-9). The ports of subcutaneous devices have internal mechanisms that open when needles are inserted and close when needles are removed. Blood from one port flows from the body to the HD machine and returns to the body via the other port. These devices may be ideal for patients waiting for permanent access placement or a kidney transplant.

Hemodialysis Nursing Care. Many drugs, such as antibiotics, are *dialyzable* (i.e., can be partially removed from the blood during dialysis) and should not be administered just before or during dialysis. Vasoactive drugs can cause hypotension during HD and may also be held until after treatment. Coordinate with the physician to assess the patient's drug regimen and determine which drugs should be held until after HD treatment. Table 71-12 lists common dialyzable and vasoactive drugs that should be given after rather than before HD.

Post-Dialysis Care. Closely monitor the patient immediately and for several hours after dialysis for any side effects from the treatment. Common problems include hypotension, headache, nausea, malaise, vomiting, dizziness, and muscle cramps.

Obtain vital signs and weight for comparison with predialysis measurements. Blood pressure and weight are expected to be reduced as a result of fluid removal. Hypotension may require rehydration with IV fluids, such as normal

TABLE 71-12 DIALYZABLE AND VASOACTIVE DRUGS

Dialyzable Drugs
Aminoglycosides

- Amikacin
- Gentamicin
- Tobramycin

Antiviral Agents

- Acyclovir
- Ganciclovir

Penicillins

- Amoxicillin
- Ampicillin
- Cloxacillin
- Dicloxacillin
- Mezlocillin
- Penicillin G
- Ticarcillin

Anticonvulsants

- Ethosuximide
- Gabapentin
- Phenobarbital

Cephalosporins

- Cefaclor
- Cefazolin
- Cefoxitin
- Ceftizoxime
- Ceftriaxone
- Cefuroxime

Antituberculosis Agents

- Ethambutol
- Isoniazid

Miscellaneous

- Aztreonam
- Cimetidine
- Vitamins

Vasoactive Drugs
Antidysrhythmics

- Flecainide
- Lidocaine
- Procainamide
- Quinidine

Antihypertensives

- Atenolol
- Captopril
- Diltiazem
- Enalapril
- Lisinopril
- Methyldopa
- Nifedipine
- Propranolol
- Verapamil

Narcotics

- Codeine
- Morphine

Sedatives

- Midazolam
- Phenobarbital
- Propofol

Vasodilators

- Hydralazine
- Nitroglycerin
- Nitroprusside

CHART 71-9 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Caring for the Patient Undergoing Hemodialysis

- Weigh the patient before and after dialysis.
- Know the patient's dry weight.
- Discuss with the health care provider whether any of the patient's drugs should be withheld until after dialysis.
- Be aware of events that occurred during previous dialysis treatments.
- Measure blood pressure, pulse, respirations, and temperature.
- Assess for symptoms of orthostatic hypotension.
- Assess the vascular access site.
- Observe for bleeding.
- Assess the patient's level of consciousness.
- Assess for headache, nausea, and vomiting.

short periods with low blood flows so that rapid changes in plasma composition are avoided.

! NURSING SAFETY PRIORITY**Critical Rescue**

Assess for and document symptoms of disequilibrium syndrome (headache, nausea, vomiting, restlessness, decreased level of consciousness, seizures, coma) during and after HD, because early recognition and treatment with anticonvulsants and barbiturates may prevent a life-threatening situation.

Infectious diseases transmitted by blood transfusion are a serious complication of long-term HD. Two of the most serious blood-transmitted infections are hepatitis and human immune deficiency virus (HIV).

Hepatitis infection (B and C) in patients with chronic kidney disease (CKD) has decreased because the use of erythropoietin has reduced the need for blood transfusions to maintain red blood cell counts. Hepatitis is a problem because of the blood access and the risk for contamination during HD. The viruses can be transmitted through the use of contaminated needles or instruments, by entry of contaminated blood through open wounds in the skin or mucous membranes, or through transfusions with contaminated blood. Monitor all patients receiving HD for manifestations of hepatitis (see [Chapter 61](#)).

HIV is a bloodborne virus that poses some risk for patients undergoing HD. Fortunately, the risks for HIV transmission are reduced by the consistent practice of Standard Precautions, routine screening of donated blood for HIV, and decreased need for blood transfusions for patients with CKD and ESKD. Patients who have been undergoing HD or received frequent transfusions during the early to mid-1980s are at risk for acquired immune deficiency syndrome (AIDS) (see also [Chapter 21](#)).

CONSIDERATIONS FOR OLDER ADULTS

In 2007, the occurrence of ESKD in patients ages 75 years or older increased to more than 25% of patients beginning ESKD therapy (USRDS, 2010). The overall mean age for new patients is 64.6 years. ESKD incidence caused by diabetes and hypertension continues to grow in older adults. Patients older than 65 years who are receiving HD are more at risk for dialysis-induced hypotension. These patients require more frequent monitoring during and after dialysis.

saline. The patient's temperature may also be elevated because the dialysis machine warms the blood slightly. If he or she has a fever, sepsis may be present and a blood sample is needed for culture and sensitivity.

The heparin required during HD increases the clotting time, which increases the risk for excessive bleeding. All invasive procedures must be avoided for 4 to 6 hours after dialysis. Continually monitor the patient for hemorrhage during and for 1 hour after dialysis ([Chart 71-9](#)).

Complications of Hemodialysis. Many fluid-related and infectious complications can occur from HD. The most common complications include disequilibrium syndrome and viral infections.

Dialysis disequilibrium syndrome may develop during HD or after HD has been completed. The cause appears to be the rapid decrease in fluid volume and blood urea nitrogen (BUN) levels during HD. The change in urea levels can cause cerebral edema and increased intracranial pressure. *Neurologic symptoms can result (e.g., headache, nausea, vomiting, restlessness, decreased level of consciousness, seizures, coma, or death).* The problem may be prevented by starting HD for

TABLE 71-13 PERITONEAL DIALYSIS

ADVANTAGES	DISADVANTAGES
Easy to learn	Time-consuming exchanges
Can be done at home	Protein wasting
Ambulatory—no machine needed	Excessive glucose load, causing hyperlipidemia
When machines are used, they are small	Sterile technique required
Less stressful on the body	Presence of permanent catheter
Hemodynamic tolerance	Weight gain
Continuous process	Peritonitis risk
Better blood pressure control	Peritoneum injury risk
Less dietary and fluid restrictions	Cannot be done if patient has had many abdominal surgeries
Greater freedom in scheduling and traveling	Chronic back pain or development of hernia

Peritoneal Dialysis

Peritoneal dialysis (PD) allows exchanges of wastes, fluids, and electrolytes to occur in the peritoneal cavity. PD is slower than hemodialysis (HD), however, and more time is needed to achieve the same effect. Advantages and disadvantages are listed in Table 71-13. The use of PD has decreased and currently accounts for only 5% to 6% of dialysis (USRDS, 2010).

Patient Selection. Most patients with chronic kidney disease (CKD) can select either HD or PD. For those who are unstable, those who cannot tolerate anticoagulation, and those with chronic infection, PD is less hazardous than HD. For some patients, vascular access problems may eliminate HD as an option. At times a patient may use PD until a new arteriovenous (AV) fistula matures. PD is also often the treatment of choice for older adults because it offers more flexibility if his or her status changes frequently.

Peritoneal dialysis *cannot* be performed if peritoneal adhesions are present or if extensive intra-abdominal surgery has been performed. In these cases, the surface area of the peritoneal membrane is not sufficient for adequate dialysis exchange. Peritoneal membrane fibrosis may occur after repeated infections, which decreases membrane permeability.

Procedure. Each PD exchange process consists of three phases: fill, dwell, and drain. A siliconized rubber (Silastic) catheter is surgically placed into the abdominal cavity for infusion of dialysate (Fig. 71-10). Usually 1 to 2 L of dialysate is infused by gravity (*fill*) into the peritoneal space over a 10- to 20-minute period, according to the patient's tolerance. The fluid stays (*dwells*) in the cavity for a specified time prescribed by the physician. The fluid then flows out of the body (*drains*) by gravity into a drainage bag. The peritoneal outflow contains the dialysate and the excess water, electrolytes, and nitrogen-based waste products. The dialyzing fluid is called *peritoneal effluent* on outflow. The three phases of the process (infusion, or “fill”; dwell; and outflow, or drain) make up one PD exchange. The number and frequency of PD exchanges are prescribed by the physician, depending on manifestations and laboratory data.

Process. Peritoneal dialysis occurs through diffusion and osmosis across the semipermeable peritoneal membrane and capillaries. The peritoneal membrane is large and porous. It allows solutes and water to move from an area of higher concentration in the blood to an area of lower concentration in the dialyzing fluid (diffusion).

FIG. 71-10 Peritoneal dialysis catheter. **A**, The actual Silastic peritoneal dialysis catheter. **B**, Positioning of the Silastic catheter within the abdominal cavity.

The peritoneal cavity is rich in capillaries and is a ready access to the blood supply. The fluid and waste products dialyzed from the patient move through the blood vessel walls, the interstitial tissues, and the peritoneal membrane and are removed when the dialyzing fluid is drained from the body.

PD efficiency is affected by many factors, such as decreased peritoneal membrane permeability caused by infection or scarring and reduced capillary blood flow resulting from blood vessel constriction, vascular disease, or decreased perfusion of the peritoneum. For PD, water removal depends on the concentration of the dialysate. Increasing the dialysate glucose concentration makes the solution more hypertonic. The more hypertonic the solution, the greater the osmotic pressure (pulling pressure) for water filtration and fluid removal from the patient during an exchange. The dialysate concentration is prescribed based on the patient's fluid status.

Dialysate Additives. Heparin may be added to the dialysate to prevent clotting of the catheter or tubing. Usually intraperitoneal (IP) heparin is needed only after new catheter placement or if peritonitis occurs. IP heparin is not absorbed systemically and does not affect blood clotting.

Other agents that may be given in the dialysate include potassium and antibiotics. Commercially prepared dialysate does not contain potassium. Some patients need potassium added to the dialysate to prevent hypokalemia. Antibiotics may be given by the IP route when peritonitis is present or suspected. Potassium and antibiotics are not mixed in the same dialysate bag because interactions may reduce the antibiotic effect.

Types of Peritoneal Dialysis. Many types of PD are available, including continuous ambulatory PD, multiple-bag continuous ambulatory PD, automated PD, intermittent PD,

FIG. 71-11 Peritoneal dialysis exchange for control of fluids, electrolytes, nitrogenous wastes, blood pressure, and acid-base balance.

FIG. 71-13 A patient performing continuous ambulatory peritoneal dialysis (CAPD).

FIG. 71-12 Peritoneal membrane as dialyzing membrane for peritoneal dialysis.

and continuous-cycle PD. The type selected depends on the patient's ability and lifestyle. The two most commonly used types of PD are continuous ambulatory peritoneal dialysis and continuous cycling peritoneal dialysis.

Continuous ambulatory peritoneal dialysis (CAPD) is performed by the patient with the infusion of four 2-L exchanges of dialysate into the peritoneal cavity. Each time, the dialysate remains for 4 to 8 hours, and these exchanges occur 7 days a week (Fig. 71-11 through 71-13). During the dwell period, the patient can use a continuous connect system or a disconnect system.

With the continuous *connect* system (straight transfer set), the dialysate bag is attached to the catheter by 48-inch tubing. The empty bag and tubing are folded and worn beneath the clothing until they are used for outflow. After draining, the patient removes the bag and connects a new bag to repeat the process.

With the *disconnect* system (Y-transfer set), the patient removes the connecting tubing and empty dialysate bag after inflow and attaches a cap to the PD catheter. The disconnect system eliminates the need to wear the tubing and bag but requires opening the system two extra times with each

FIG. 71-14 Peritoneal dialysis machine circuit in automated peritoneal dialysis (APD).

exchange. The extra opening of the system increases the risk for infection.

With CAPD, no machine is necessary and no partner is required. However, it is best for a partner also trained in CAPD to be available as a support for the patient if illness occurs. Devices to assist in the safe, sterile connection of the tubing spike with the dialysate bag are available. These are useful for patients with poor vision, limited manual dexterity, or reduced hand and arm strength. CAPD allows constant removal of fluid and wastes and resembles kidney action more closely than HD. Some patients even perform their own exchanges while hospitalized.

Continuous-cycle peritoneal dialysis (CCPD) is a form of automated dialysis that uses an automated cycling machine. Exchanges occur at night while the patient sleeps. The final exchange of the night is left to dwell through the day and is drained the next evening as the process is repeated. CCPD offers the advantage of 24-hour dialysis, as in CAPD, but the sterile catheter system is opened less often.

Automated peritoneal dialysis (APD) may be used in the acute care setting, the outpatient dialysis center, or the patient's home. APD uses a cycling machine for dialysate inflow, dwell, and outflow according to preset times and volumes. A warming chamber for dialysate is part of the machine (Fig. 71-14). The functions are programmed for the patient's specific needs. A typical prescription calls for 30-minute exchanges (10/10/10 for inflow, dwell, and outflow) for a period of 8 to 10 hours. The machines have many safety monitors and alarms and are relatively simple to learn to use (Fig. 71-15).

Automated peritoneal dialysis has several advantages. It permits in-home dialysis while the patient sleeps, allowing him or her to be dialysis-free during waking hours. The incidence of peritonitis is reduced with APD because fewer connections and disconnections are needed. Also, APD can be

FIG. 71-15 A cyclor machine for automated peritoneal dialysis at home.

used to deliver larger volumes of dialysis solution for patients who need higher clearances.

Intermittent peritoneal dialysis (IPD) combines osmotic pressure gradients with true dialysis. The patient usually requires exchanges of 2 L of dialysate at 30- to 60-minute intervals, allowing 15 to 20 minutes of drain time. For most patients, 30 to 40 exchanges of 2 L three times weekly are needed. IPD treatments can be automated or manual.

Complications. Complications are possible with PD, but many can be prevented with meticulous care.

Peritonitis is the major complication of PD. The most common cause of peritonitis is connection site contamination. To prevent peritonitis, use meticulous sterile technique when caring for the PD catheter and when hooking up or clamping off dialysate bags (Chart 71-10).

Manifestations of peritonitis include cloudy dialysate outflow (effluent), fever, abdominal tenderness, abdominal

CHART 71-10 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Caring for the Patient with a Peritoneal Dialysis Catheter

- Mask yourself and your patient. Wash your hands.
- Put on sterile gloves. Remove the old dressing. Remove the contaminated gloves.
- Assess the area for signs of infection, such as swelling, redness, or discharge around the catheter site.
- Use aseptic technique:
 - Open the sterile field on a flat surface, and place two precut 4 × 4-inch gauze pads on the field.
 - Place three cotton swabs soaked in povidone-iodine on the field. Put on sterile gloves.
- Use cotton swabs to clean around the catheter site. Use a circular motion starting from the insertion site and moving away toward the abdomen. Repeat with all three swabs.
- Apply precut gauze pads over the catheter site. Tape only the edges of the gauze pads.

pain, general malaise, nausea, and vomiting. *Cloudy or opaque effluent is the earliest sign of peritonitis.* Examine all effluent for color and clarity to detect peritonitis early. When peritonitis is suspected, send a specimen of the dialysate outflow for culture and sensitivity study, Gram stain, and cell count to identify the infecting organism.

Pain during the inflow of dialysate is common when patients are first started on PD therapy. Usually this pain no longer occurs after a week or two of PD. Cold dialysate increases discomfort. Warm the dialysate bags before instillation by using a heating pad to wrap the bag or by using the warming chamber of the automated cycling machine. *Micro-wave ovens are **not** recommended for the warming of dialysate.*

Exit site and tunnel infections are serious complications. The exit site from a PD catheter should be clean, dry, and without pain or inflammation. Exit site infections (ESIs) can occur with any type of PD catheter. These infections are difficult to treat and can become chronic. They can lead to peritonitis, catheter failure, and hospitalization. Dialysate leakage and pulling or twisting of the catheter increase the risk for ESIs. A Gram stain and culture should be performed when exit sites have purulent drainage.

Tunnel infections occur in the path of the catheter from the skin to the cuff. Manifestations include redness, tenderness, and pain. ESIs are treated with antimicrobials. Deep cuff infections may require catheter removal.

Poor dialysate flow is usually related to constipation. To prevent constipation, a bowel preparation is prescribed before placement of the PD. An enema before starting PD may also prevent flow problems. Teach patients to eat a high-fiber diet and use stool softeners to prevent constipation. Other causes of flow difficulty include kinked or clamped connection tubing, the patient's position, fibrin clot formation, and catheter displacement.

Ensure that the drainage bag is lower than the patient's abdomen to enhance gravity drainage. Inspect the connection tubing and PD system for kinking or twisting. Ensure that clamps are open. If inflow or outflow drainage is still inadequate, reposition the patient to stimulate inflow or outflow. Turning the patient to the other side or ensuring that he or

she is in good body alignment may help. Having the patient in a supine low-Fowler's position reduces abdominal pressure. Increased abdominal pressure from sitting or standing or from coughing contributes to leakage at the PD catheter site.

Fibrin clot formation may occur after PD catheter placement or with peritonitis. Milking the tubing may dislodge the fibrin clot and improve flow. An x-ray is needed to identify PD catheter placement. If displacement has occurred, the physician repositions the PD catheter.

Dialysate leakage is seen as clear fluid coming from the catheter exit site. When dialysis is first started, small volumes of dialysate are used. It may take patients 1 to 2 weeks to tolerate a full 2-L exchange without leakage around the catheter site. Leakage occurs more often in obese patients, those with diabetes, older adults, and those on long-term steroid therapy. During periods of catheter leak, patients may require hemodialysis (HD) support.

Other complications of PD include bleeding, which is expected when the catheter is first placed, and bowel perforation, which is serious. When PD is first started, the outflow may be bloody or blood tinged. This condition normally clears within a week or two. After PD is well-established, the effluent should be clear and light yellow. Observe for and document any change in the color of the outflow. Brown-colored effluent occurs with a bowel perforation. If the outflow is the same color as urine and has the same glucose level, a bladder perforation is probable. Cloudy or opaque effluent indicates infection.

Nursing Care During Peritoneal Dialysis. In the hospital setting, PD is routinely started and monitored by the nurse. Before the treatment, assess baseline vital signs, including blood pressure, apical and radial pulse rates, temperature, quality of respirations, and breath sounds. Weigh the patient, always on the same scale, before the procedure and at least every 24 hours while receiving treatment. Weight should be checked after a drain and before the next fill to monitor the patient's "dry weight." Baseline laboratory tests, such as electrolyte and glucose levels, are obtained before starting PD and are repeated at least daily during the PD treatment.

Continually monitor the patient during PD. Take and record vital signs every 15 to 30 minutes. Assess for signs of respiratory distress, pain, or discomfort. Check the dressing around the catheter exit site every 30 minutes for wetness during the procedure. Monitor the prescribed dwell time, and initiate outflow. Assess blood glucose levels in patients who absorb glucose.

Observe the outflow pattern (outflow should be a continuous stream after the clamp is completely open). Measure and record the total amount of outflow after each exchange. Maintain accurate inflow and outflow records when hourly PD exchanges are performed. When outflow is less than inflow, the difference is retained by the patient during dialysis and is counted as fluid intake. Weigh the patient daily to monitor fluid status.

Kidney Transplantation

Dialysis and kidney transplant are life-sustaining *treatments* for end-stage kidney disease (ESKD). Kidney transplant is not considered a "cure." Each patient, in consultation with a nephrologist, determines which type of therapy is best suited to his or her physical condition and lifestyle. During 2009,

17,513 kidney transplants had been performed in the United States. In 2010 about 159,000 people were awaiting kidney transplant in North America. The median time on the waiting list was 678 days (USRDS, 2010).

Candidate Selection Criteria. Candidates for transplantation must be free of medical problems that might increase the risks from the procedure. Candidates are accepted for kidney transplant up to 70 years of age. Patients older than 70 years are considered for transplant on an individual basis because complications are more common in the older adult.

The patient is thoroughly assessed before he or she is considered for a kidney transplant. Patients who have advanced, uncorrectable cardiac disease are excluded from the procedure because these problems are made worse by transplantation. Other conditions that preclude kidney transplant include metastatic cancer, chronic infection, and severe psychosocial problems such as alcoholism or chemical dependency. Long-standing pulmonary disease increases the risk for complications and death from respiratory infections. Patients with diseases of the GI system may require treatment before consideration for transplantation. Problems such as peptic ulcer and diverticulosis are made worse by the large doses of steroids used after the surgery.

The urinary system is completely evaluated to ensure normal urine flow. Many patients with ESKD have not used their lower urinary tract for years, and ureteral or bladder problems may require surgical correction before a kidney is transplanted.

Patients with a recent history of cancer are treated with dialysis because of the shortage of donor organs and the uncertain life expectancy of these patients. In addition, the drugs used after the procedure increase the risk for cancer recurrence. If more than 2 to 5 years have passed since eradication of the cancer, the patient can be considered for a transplant.

Diabetes mellitus and other endocrine problems cause even greater risks. Patients with these problems can have a kidney transplant, but they require intense observation and management to limit complications. Other complicating conditions are considered on an individual basis, depending on the patient's current health status. Kidney transplantation can be considered for most patients with ESKD and is the optimal therapy for many people. Most people who have undergone this procedure are satisfied with their quality of life for years after the transplant.

Donors. Kidney donors may be living donors (either related or unrelated to the patient), non-heart-beating donors (NHBDs), and cadaveric donors. The available kidneys are matched on the basis of tissue type similarity between the donor and the recipient. Living donors are most often blood relatives, but unrelated donors have been used. NHBDs are persons declared dead by cardiopulmonary criteria. Kidneys from NHBDs are removed (harvested) immediately after death in cases in which patients have previously given consent for organ donation. If immediate removal must be delayed, the organ is preserved by infusing a cool preservation solution into the abdominal aorta after death is declared and until surgery can be performed. Cadaveric donors are usually individuals who suffered irreversible brain injury and brain death, most often as a result of trauma. These donors are maintained with mechanical ventilation and must have sufficient renal perfusion for the kidneys to remain viable.

FIG. 71-16 An example of a paired exchange kidney donation. Donor 1 is related to or acquainted with recipient 1 and has agreed to donate a kidney but is not a blood type or tissue type match with recipient. Donor 1 is compatible with recipient 2 and agrees to donate a kidney to recipient 2 if donor 2 agrees to donate a kidney to recipient 1.

The size of the kidney is seldom a problem in adults. Kidneys transplanted from children become larger to meet adult needs within a few months.

Organs from living *related* donors (LRDs) have the highest rates of kidney graft survival (90%). Donors are usually at least 18 years old and are seldom older than 65 years. Physical criteria for donors include:

- Absence of systemic disease and infection
- No history of cancer
- No hypertension or kidney disease
- Adequate kidney function as determined by diagnostic studies

LRDs must express a clear understanding of the surgery and a willingness to give up a kidney. Some transplant centers require a psychiatric evaluation to assess the donor's motivation.

A list-paired exchange donation can be done when two kidney donor/recipient pairs have blood types that are not compatible within one pair. The two recipients trade donors so that each recipient can receive a kidney with a compatible blood type and tissue type (Fig. 71-16). Once the evaluations of all donors and recipients are completed, the two kidney transplant operations are scheduled to occur simultaneously (United Network for Organ Sharing [UNOS], 2011).

Because of advances in immunosuppressant therapy and medical management, the United Network of Organ Sharing (UNOS) reported 1-year kidney transplant graft survival to be almost 95% for all centers in the United States during 2010 (UNOS, 2011).

Preoperative Care. Many issues related to patient health and the actual transplant procedure must be addressed before surgery.

FIG. 71-17 Placement of a transplanted kidney in the right iliac fossa.

Immunologic studies are needed because the major barrier to transplant success after a suitable donor kidney is available is the body's ability to reject "foreign" tissue. This immunologic process can attack the transplanted kidney and destroy it. For immunologic problems to be overcome, tissue typing is performed on all candidates. These studies include simple blood typing and human leukocyte antigen (HLA) studies, as well as other tests. A donated kidney *must* come from a donor who is the same blood type as the recipient. The HLAs are the main immunologic feature used to match transplant recipients with compatible donors. The more similar the antigens of the donor are to those of the recipient, the more likely the transplant will be successful and rejection will be avoided (see Chapter 19).

Surgical team members for transplantation include circulating and scrub nurses, clinical nurse specialists, transplant surgeons, anesthesiologists, and nephrologists. Nursing actions before surgery include teaching about the procedure and care after surgery, in-depth patient assessment of patient readiness and ability to adhere to the plan of care, coordination of diagnostic tests, and development of treatment plans. See Chapter 16 for more discussion of standard preoperative nursing care.

The patient usually requires dialysis within 24 hours of the surgery. In addition, the recipient often receives a blood transfusion before surgery. Usually blood from the kidney donor is transfused into the recipient. This procedure increases graft survival of organs from living related donors (LRDs).

Operative Procedures. The donor nephrectomy procedure varies depending on whether the donor is a non-heart-beating donor (NHBD), cadaveric donor, or living donor. The NHBD or cadaveric donor nephrectomy is a sterile autopsy procedure performed in the operating room. All arterial and venous vessels and a long piece of ureter are preserved. After removal, the kidneys are preserved until time for implantation into the recipient. The technique for kidney removal from living donors is a delicate procedure that lasts

3 to 4 hours. A flank incision is used, and care is taken to avoid scarring. Donors often have more pain after surgery than do recipients. They also need nursing care and support for the psychological adjustment to loss of a body part.

Transplantation surgery usually takes 4 to 5 hours. The new kidney is usually placed in the right or left anterior iliac fossa (Fig. 71-17) instead of the usual kidney position. This placement allows easier connection of the ureter and the renal artery and vein. It also allows for easier kidney palpation. The recipient's own failed kidneys are not removed unless chronic kidney infection is present or, as in the case of polycystic kidney disease, the nonfunctioning, enlarged kidneys cause pain. After surgery, the patient is taken to the postanesthesia care unit and then, when stable, to a designated unit in the transplant center, to a critical care unit, or to a telemetry unit.

Postoperative Care. Care of the recipient after surgery requires that nurses be knowledgeable about the expected clinical findings and potential complications. Nursing care includes ongoing physical assessment, especially evaluation of kidney function. The transplant recipient requires close attention because the immunosuppressive drug therapy used to prevent tissue rejection impairs healing and increases the risk for infection.

Urologic management is essential to graft success. A large-bore indwelling (Foley) catheter is placed for accurate measurements of urine output and decompression of the bladder. Decompression prevents stretch on sutures and ureter attachment sites on the bladder.

Assess urine output at least hourly during the first 48 hours. An abrupt decrease in urine output may indicate complications such as rejection, acute kidney injury (AKI), thrombosis, or obstruction. Examine the urine color. The urine is pink and bloody right after surgery and gradually returns to normal over several days to several weeks, depending on kidney function. Obtain daily urine specimens for urinalysis, glucose measurement, the presence of acetone, specific gravity measurement, and culture (if needed).

Occasionally, a continuous bladder irrigation is prescribed to decrease blood clot formation, which could increase pressure in the bladder and endanger the graft. Perform routine catheter care, according to agency policy, to reduce catheter contamination. The catheter is removed as soon as possible to avoid infection, usually 3 to 7 days after surgery. After surgery, the function of the transplanted kidney (graft) can result in either oliguria or diuresis. Oliguria may occur as a result of ischemia and AKI, rejection, or other complications. To increase urine output, the physician may prescribe diuretics and osmotic agents, such as mannitol. Closely monitor the patient's fluid status because fluid overload can cause hypertension, heart failure, and pulmonary edema. Evaluate his or her fluid status by weighing daily, measuring blood pressure every 2 to 4 hours, and measuring intake and output.

Instead of oliguria, the patient may have diuresis, especially with a kidney from a living related donor (LRD). Carefully monitor intake and output, and observe for serum electrolyte imbalances, such as low potassium and sodium levels. Excessive diuresis may cause hypotension.

! NURSING SAFETY PRIORITY

Critical Rescue

Notify the physician immediately about hypotension or excessive diuresis in the patient who has had a kidney transplant, because hypotension reduces blood flow and oxygen to the new kidney, threatening graft survival.

Complications. Many complications are possible after kidney transplantation. Early detection and intervention improve the chances of graft survival.

Rejection is the most serious complication of transplantation and is the leading cause of graft loss. A reaction occurs between the tissues of the transplanted kidney and the antibodies and cytotoxic T-cells in the recipient's blood. These substances treat the new kidney as a foreign invader and cause tissue destruction, thrombosis, and eventual kidney necrosis.

The three types of rejection are hyperacute, acute, and chronic. Acute rejection is the most common type with kidney transplants. It is treated with increased immunosuppressive therapy and often can be reversible. Rejection is diagnosed by manifestations, a renal scan, and kidney biopsy. Table 71-14 lists the features of the three types of rejection. Chapter 19 discusses their causes and treatment.

Acute tubular necrosis (ATN) after surgery can occur as a result of hypoxic damage when transplantation is delayed after kidneys have been harvested. These patients may need dialysis until adequate urine output returns and the blood urea nitrogen (BUN) and creatinine levels normalize. ATN is often difficult to distinguish from acute rejection, and patients need to undergo weekly biopsies to assess the need for further drug therapy if rejection is occurring.

Thrombosis of the major renal blood vessels may occur during the first 2 to 3 days after the transplant. A sudden decrease in urine output may signal impaired perfusion resulting from thrombosis. Ultrasound examination of the kidney may show decreased or absent blood supply. Emergency surgery is required to prevent ischemic damage or graft loss.

TABLE 71-14 A COMPARISON OF HYPERACUTE, ACUTE, AND CHRONIC POST-TRANSPLANT REJECTION

HYPERACUTE REJECTION	ACUTE REJECTION	CHRONIC REJECTION
Onset		
Within 48 hr after surgery	1 wk to 2 yr postoperatively (most common in first 2 wk)	Occurs gradually during a period of months to years
Clinical Manifestations		
Increased temperature	Oliguria or anuria	Gradual increase in BUN and serum creatinine levels
Increased blood pressure	Temperature over 100° F (37.8° C)	
Pain at transplant site	Increased blood pressure Enlarged, tender kidney Lethargy Elevated serum creatinine, BUN, potassium levels Fluid retention	Fluid retention Changes in serum electrolyte levels Fatigue
Treatment		
Immediate removal of the transplanted kidney	Increased doses of immunosuppressive drugs	Conservative management until dialysis is required

BUN, Blood urea nitrogen.

Renal artery stenosis may result in hypertension. Other manifestations include a bruit over the artery anastomosis site and decreased kidney function. A renal scan can quantify the blood flow to the kidney. The involved artery may be repaired surgically or by balloon angioplasty in the radiology department. The decision to perform a balloon repair is determined by the amount of healing time after the surgery.

Other vascular problems include vascular leakage or thrombosis, both of which require an emergency transplant nephrectomy.

Other complications may involve the surgical wound or urinary tract. Wound problems, such as hematomas, abscesses, and lymphoceles (lymphocyte cysts containing lymph fluid), increase the risk for infection and exert pressure on the new kidney. Infection is a major cause of death in the transplant recipient. Prevention of infection is essential. Strict aseptic technique and handwashing must be rigorously enforced. Transplant recipients may not have the usual manifestations of infection because of the immunosuppressive therapy. Low-grade fevers, mental status changes, and vague reports of discomfort may be the only manifestations before sepsis. Always consider the possibility of infection with any patient after a kidney transplant. Urinary tract complications include ureteral leakage, fistula, or obstruction; stone formation; bladder neck contracture; and graft rupture. Surgical intervention may be required.

Immunosuppressive Drug Therapy. The success of kidney transplantation depends on changing the patient's immunologic response so that the new kidney is not rejected as a

foreign organ. Immunosuppressive drugs protect the transplanted organ and are taken by the transplant recipient for the rest of his or her life. These drugs include corticosteroids, anti-lymphocyte preparations, monoclonal antibodies, and cyclosporine (Cyclosporin A). Chapter 19 discusses the mechanisms of action for these agents and the associated patient responses. Patients taking these drugs are at an increased risk for death by viral, fungal, bacterial, or protozoal infection.

Many patients do not follow the regimen correctly and are at high risk for losing the transplanted kidney. Work with the patient to ensure adherence to the drug regimen.

NURSING SAFETY PRIORITY

Action Alert

Teach patients and families about the importance of adhering to the anti-rejection drug regimen to prevent transplant rejection.

DECISION-MAKING CHALLENGE

Safety; Teamwork and Collaboration

The patient is a 62-year-old man with ESKD who has been on hemodialysis for 3 years while waiting for a kidney transplant. He expresses frustration with the wait from time to time and has told you that he fears that he will be considered too old to receive a kidney if much more time goes by. Today, he tells you that he won't be coming to the hemodialysis clinic anymore because he is taking a trip. When you ask him if he would like you to arrange dialysis for him on his trip, he tells you that won't be necessary. He doesn't make eye contact with you when you ask him why it won't be necessary. After a few minutes, he tells you that he is flying to India tonight and has paid to have a kidney transplant this week.

1. How should you respond to this statement?
2. Does the patient have the right to do this?
3. Is he right in thinking that he may be considered too old to receive a kidney?
4. Should you call UNOS and have his name taken off the kidney transplant waiting list?

Community-Based Care

Home Care Management

Because of the complex nature of CKD, its progressive course, and many treatment options, a case manager is helpful in planning, coordinating, and evaluating care. As kidney disease progresses, the patient is seen by a physician or nurse practitioner regularly and may be hospitalized often. Together with the dietitian and social worker, evaluate the home environment and determine equipment needs before discharge. Once the patient is discharged, home care nurses direct care and monitor progress. Chart 71-11 provides a focused assessment guide for the patient after transplantation.

Provide health teaching about the diet in kidney disease and the progression of disease. As CKD approaches end-stage kidney disease (ESKD), one of these courses of treatment is chosen: hemodialysis (HD), peritoneal dialysis (PD), or transplantation. For each form of treatment, the patient and partner must learn about the procedures and consider his or her personal lifestyle, support systems, and methods of coping. Decision making about treatment type or even whether to pursue treatment is difficult for patients and

CHART 71-11 FOCUSED ASSESSMENT

The Patient with Chronic Kidney Disease

Assess cardiovascular and respiratory status, including:

- Vital signs, with special attention to blood pressure
- Presence of S_3 or pericardial friction rub
- Presence of chest pain
- Presence of edema (periorbital, pretibial, sacral)
- Jugular vein distention
- Presence of dyspnea
- Presence of crackles, beginning at the bases and extending upward

Assess nutritional status, including:

- Weight gain or loss
- Presence of anorexia, nausea, or vomiting

Assess kidney status, including:

- Amount, frequency, and appearance of urine (in non-anuric patients)
- Presence of bone pain
- Presence of hyperglycemia secondary to diabetes

Assess hematologic status, including:

- Presence of petechiae, purpura, ecchymoses
- Presence of fatigue or shortness of breath

Assess gastrointestinal status, including:

- Presence of stomatitis
- Presence of melena

Assess integumentary status, including:

- Skin integrity
- Presence of pruritus
- Presence of skin discoloration

Assess neurologic status, including:

- Changes in mental status
- Presence of seizure activity
- Presence of sensory changes
- Presence of lower extremity weakness

Assess laboratory data, including:

- BUN
- Serum creatinine
- Creatinine clearance
- CBC
- Electrolytes

Assess psychosocial status, including:

- Presence of anxiety
- Presence of maladaptive behavior

BUN, Blood urea nitrogen; CBC, complete blood count.

families. Provide information and emotional support to assist patients with these decisions.

Teach patients who select hemodialysis (HD) about the machine and vascular access care. If in-home HD is selected, preparations are needed for the appropriate equipment, including a water treatment system. Regardless of whether the treatment occurs at home or in a center, provide ongoing assessment and health teaching to promote independence at home.

The patient receiving PD needs extensive training in the procedure. He or she also needs help in obtaining equipment and the many supplies needed. Home care nurses assess patients, monitor vital signs, assess adherence with drug and diet regimens, and monitor for manifestations of peritonitis.

The nurse plays a vital role in the long-term care of the patient with a kidney transplant. This patient is usually discharged 1 to 2 weeks after surgery. Facilitate acceptance and understanding of the anti-rejection drug regimen as a part of

daily life. Carefully monitor for signs of graft rejection and for complications, such as infection.

Teaching for Self-Management

Instruct patients and family members in all aspects of nutrition therapy, drug therapy, and complications. Teach them to report complications, such as fluid overload and infection. When a patient requires a more advanced form of therapy, such as dialysis or transplantation, focus teaching on the chosen type of intervention.

Hemodialysis (HD) is the most complex form of therapy for the patient and family to understand. Even if patients receive HD in a dialysis center instead of at home, they are expected to have some knowledge of the HD machine. The patient or a family member must be taught to care for the vascular access and to report signs of infection and stenosis. Those who plan to have in-home HD will need a partner. Both the patient and the partner must be taught the entire process of HD and must be able to perform it independently before the patient is discharged.

Peritoneal dialysis (PD) involves extensive health teaching. This instruction can be given to the patient alone or to the patient and a family member if the patient cannot perform the procedure. Emphasize sterile technique because peritonitis is the most common complication of PD. Instruct patients to report any manifestation of peritonitis, especially cloudy effluent and abdominal pain. If peritonitis develops, teach patients how to give themselves antibiotics by the intraperitoneal (IP) route. Stress the importance of completing the antibiotic regimen. Remind patients that repeated episodes of peritonitis can reduce the effectiveness of PD, which may require the transfer to HD.

The patient receiving a kidney transplant also needs extensive health teaching. Provide instruction about drug regimens, home monitoring, immunosuppression, manifestations of rejection, infection, and prescribed changes in the diet and activity level.

Psychosocial Preparation

Provide psychological support for the patient and family. Help the patient adjust to the diagnosis of kidney failure and eventually accept the treatment regimens.

Many patients view dialysis as a cure instead of lifelong management. For many patients, the reduction of uremic symptoms in the first weeks after starting dialysis treatment creates a sense of well-being (the “honeymoon” period). They feel better physically, and their mood may be happy and hopeful. At this time they tend to overlook the discomfort and inconvenience of dialysis. Use this time to begin health care teaching. Stress that, although the uremic symptoms are reduced, they should not expect a complete return to the previous state of well-being.

Many patients become discouraged during the first year of treatment. This mood state may last a few months to a year or longer. The difficulties of incorporating dialysis into daily life are staggering, and patients may become depressed as

problems occur. They may struggle with the idea of having to be permanently dependent on a disruptive therapy. Patients may feel helpless and dependent. Some people retreat into complete or partial denial of the disease and the need for treatment. They may deny the need for dialysis or may not adhere to drug therapy and diet restrictions. Monitor any behaviors that may contribute to nonadherence, and suggest psychiatric referrals. Help the patient and family focus on the positive aspects of the treatments. Continue health care education with patients as active participants and decision makers.

Most patients with CKD eventually enter a phase of acceptance or resignation. The idea of a chronic illness may be devastating for some people, and each person reacts differently. To make this long-term adaptation, the patient must adjust to continuous change. Specific concerns depend on the patient's health and particular treatment method.

After patients have accepted or become resigned to the chronic aspect of their disease, they usually attempt to return to their previous activities. Resuming the previous level of activity, however, may not be possible. Help patients set realistic goals that allow them to lead active, productive lives.

Health Care Resources

Professionals from many disciplines are resources for the patient with kidney failure. Home care nurses monitor the patient's status and evaluate maintenance of the prescribed treatment regimen (HD or PD). Those with advanced disease may need a home care aide to help perform ADLs. Social services are often involved because of the complex process of applying for financial aid to pay for the required medical care. A physical therapist may be beneficial in helping improve the patient's functional health. A dietitian can assist the patient and family members in understanding the special dietary needs. A psychiatric evaluation may be needed if depressive symptoms are present. Clergy and pastoral care specialists offer spiritual support.

Patients with CKD are routinely followed by a physician, usually a nephrologist. Organizations such as the National Kidney Foundation (NKF), the American Kidney Fund, and the National Association of Patients on Hemodialysis and Transplantation (NAPHT) may be helpful to patients and families.

EVALUATION: OUTCOMES

Evaluate the care of the patient with CKD based on the identified priority patient problems. The expected outcomes are that with appropriate management the patient should:

- Achieve and maintain appropriate fluid volume
- Maintain an adequate nutritional status
- Use effective coping strategies
- Report an absence of physical manifestations of anxiety

Specific indicators for these outcomes are listed for each priority problem under the Planning and Implementation section (see earlier).

NURSING CONCEPT REVIEW

What might you NOTICE if the patient is experiencing altered urinary elimination as a result of acute kidney injury?

- Patient urinates infrequently.
- Patient reports back or flank pain.
- Urine may be darker, smoky, or have obvious blood in it.

What should you INTERPRET and how should you RESPOND to a patient experiencing altered urinary elimination as a result of acute kidney injury?

Perform and interpret physical assessment, including:

- Ask how long manifestations have been present.
- Determine fluid intake and output volumes.
- Weigh the patient, and ask whether this weight is more or less than the usual weight.
- Assess for tachycardia.
- Assess for pulmonary congestion.
- Check for presence of generalized and dependent edema.

- Interpret laboratory values:
 - Complete blood count with hemoconcentration
 - BUN and serum creatinine levels elevated
 - Serum potassium level elevated
 - Serum osmolarity abnormal

Respond by:

- Ensuring hemodynamic stability
- Monitoring urine output
- Monitoring for fluid overload

On what should you REFLECT?

- Observe patient for evidence of improved urine output (see [Chapter 68](#)).
- Think about what may have caused this problem and what steps could be taken to prevent a similar episode.
- Think about what patient teaching focus could help reduce the risk for future acute kidney injury.

GET READY FOR THE NCLEX® EXAMINATION!

KEY POINTS

Review these Key Points for each NCLEX Examination Client Needs Category.

Safe and Effective Care Environment

- Use sterile technique when cannulating a vascular access or connecting peritoneal dialysis tubing.
- Handle patients with chronic kidney disease gently to prevent fractures.
- Assess all patients at risk for dehydration or hypovolemia for adequacy of kidney perfusion.
- Avoid taking blood pressure measurements or drawing blood from an arm with a vascular access (AV fistula or graft).
- Do not use an AV fistula or graft site to give IV fluids.

Health Promotion and Maintenance

- Encourage patients with chronic kidney disease or kidney failure to follow fluid and dietary restrictions regarding sodium, potassium, and protein.
- Teach patients the expected side effects, any adverse reactions to prescribed drugs, and when to contact the prescriber.
- Teach patients using peritoneal dialysis the manifestations of peritonitis.
- Teach patients on immunosuppressive therapy to assess themselves daily for fever, general malaise, and nausea or vomiting.

Psychosocial Integrity

- Allow patients the opportunity to express concerns about the risk for death and the disruption of lifestyle as a result of treatment for kidney failure.
- Use language and terminology that are comfortable for the patient.
- Assess the patient for depression and nonacceptance of the diagnosis or treatment plan.
- Refer patients to community resources and support groups.

Physiological Integrity

- Report immediately any condition that obstructs urine flow.
- Collaborate with the dietitian to teach patients about needed fluid, sodium, potassium, or dietary protein restriction.
- Teach patients in the early stages of chronic kidney disease the manifestations of dehydration.
- Teach patients in the later stages of chronic kidney disease the manifestations of fluid overload and hyperkalemia.
- Avoid all invasive procedures within 4 to 6 hours after the patient has undergone hemodialysis.
- Use meticulous sterile technique when caring for the peritoneal dialysis catheter and when hooking up or clamping off dialysate bags.

CONCEPT OVERVIEW

Sexuality

Unlike the physiologic human needs introduced in other section openers of this text, *sexuality* is a complex integration of many physiologic, emotional, social, and cultural aspects of well-being. It is closely associated with self-concept, self-esteem, role relationships, sexual response, and reproduction. Sexuality comprises other related human needs, such as belonging, intimacy (e.g., touching, kissing), sharing, and caring. When these needs are met, a person is sexually healthy (Fig. 1).

Sexuality, therefore, is a vital part of one's holistic being from birth to death. During the stages of human development, a person's attitudes, beliefs, and values related to sexuality are influenced and shaped by the environment, including family, friends, and society. For example, cultural beliefs affect the nature of physical sexual pleasure. The media also play a large role in developing sexual pleasure on sexuality. Some societies, such as the United States, tend to value youth and beauty more than aging and wisdom. As a result, people in these societies may feel less physically attractive and desirable for intimacy and belonging as they age.

Various external and internal risk factors can alter or impair sexual health. In many cases, they cause physical sexual dysfunction, which then affects emotional needs such as self-esteem (Fig. 2). These factors include:

- Stages of human development
- Physical health problems
- Drugs
- Mental/behavioral health problems

The *stages of human development* typically influence human sexuality, especially when menopause occurs in middle adulthood. Although each woman's response is different, menopause may result in a decreased libido (desire for sexual contact or intercourse). Relationships with her sexual partner(s) are altered, and interpersonal conflict can occur.

Physical health problems also can negatively affect sexual health. For example, chronic pain may cause decreased physical contact and a lowered self-concept along with chronic fatigue and decreased energy. Sexual dysfunction commonly occurs in people with chronic diseases such as diabetes and hypertension. Reproductive diseases (e.g., sexually transmitted diseases, testicular cancer) and their treatments (e.g., radiation therapy, surgery) can also affect sexuality, both physically and emotionally. Physical trauma such as spinal cord injury may prevent a person from having sexual intercourse.

Certain prescription or recreational *drugs* can cause impotence (inability to have an erection) or infertility. Alcohol and many antihypertensive agents, antidepressants, and illicit drugs interfere with sexual function in men.

Mental/behavioral health problems can also result in altered sexual health. Common examples include depression and severe anxiety states. In some cases, concern about physical performance can lead to sexual dysfunction.

LEARNING OUTCOMES**Health Promotion and Maintenance**

1. Teach patients about recommended guidelines for selected reproductive screening tests.
2. Teach pre- and post-test care for diagnostic testing for the reproductive system.

Psychosocial Integrity

3. Identify general psychological responses to reproductive health problems.

Physiological Integrity

4. Briefly review the anatomy and physiology of the male and the female reproductive systems.

5. Identify reproductive changes associated with aging and their implications for nursing care.
6. Perform a focused physical assessment of the patient with male or female reproductive system problems.
7. Explain the use of laboratory testing for patients with suspected or actual reproductive health problems.
8. Develop a teaching plan for a patient undergoing endoscopic studies for reproductive health problems.

FIG. 72-1 Internal female genitalia.

The nurse is typically the first health care professional to assess the patient with a reproductive system health problem or hear a patient's concern about a reproductive problem. These problems often affect the need for *sexuality*, both its physical and psychosocial aspects, and are difficult for many people to discuss. Assessment of the male and the female reproductive systems should be part of every complete physical assessment. *Be aware of and sensitive to differences in sexual orientation and practices.*

This chapter reviews the focused reproductive system assessment that a nurse generalist performs. An advanced practice nurse or other health care provider performs the comprehensive reproductive examination. A more detailed discussion of human sexuality is found in a fundamentals or basic nursing text.

ANATOMY AND PHYSIOLOGY REVIEW

Structure and Function of the Female Reproductive System

The female reproductive system is located both outside (external) and inside (internal) the body.

External Genitalia

The external female genitalia, or **vulva**, extend from the mons pubis to the anal opening. The **mons pubis** is a fat pad that covers the symphysis pubis and protects it during **coitus** (sexual intercourse).

The **labia majora** are two vertical folds of adipose tissue that extend posteriorly from the mons pubis to the perineum. The size of the labia majora varies depending on the amount of fatty tissue present. The skin over the labia majora is

usually darker than the surrounding skin and is highly vascular. It protects inner vulval structures and enhances sexual arousal.

The labia majora surround two thinner, vertical folds of reddish epithelium called the **labia minora**. The labia minora are highly vascular and have a rich nerve supply. Emotional or physical stimulation produces marked swelling and sensitivity. Numerous sebaceous glands in the labia minora lubricate the entrance to the vagina. The **clitoris** is a small, cylindric organ that is composed of erectile tissue with a high concentration of sensory nerve endings. During sexual arousal, the clitoris becomes larger and increases sexual sensation.

The **vestibule** is a longitudinal area between the labia minora, the clitoris, and the vagina that contains Bartholin glands and the openings of the urethra, Skene's glands (para-urethral glands), and vagina. The two Bartholin glands, located deeply toward the back on both sides of the vaginal opening, secrete lubrication fluid during sexual excitement. Their ductal openings are usually not visible.

The area between the vaginal opening and the anus is the **perineum**. The skin of the perineum covers the muscles, fascia, and ligaments that support the pelvic structures.

Internal Genitalia

The internal female genitalia are shown in Fig. 72-1. The **vagina** is a hollow tube that extends from the vestibule to the uterus. In addition to being the channel for the passage of the menstrual flow, the vagina allows for insertion of the penis during intercourse and passage of the fetus during a vaginal birth. Reduced estrogen levels occurring during menopause cause the vaginal wall to become dry, thinner, and smoother. The vagina then atrophies and is prone to pathogenic growth, resulting in a variety of types of infections.

The amounts of glycogen and lubricating fluid secreted by the vaginal cells are influenced by ovarian hormones. The normal vaginal bacteria (flora) interact with the secretions to produce lactic acid and maintain an acidic pH (3.5 to 5) in the vagina. This acidity helps prevent infection in the vagina.

At the upper end of the vagina, the uterine cervix projects into a cup-shaped vault of thin vaginal tissue. The recessed pockets around the cervix permit palpation of the internal pelvic organs. The posterior area provides access into the peritoneal cavity for diagnostic or surgical purposes.

The uterus (or “womb”) is a thick-walled, muscular organ attached to the upper end of the vagina. This inverted pear-shaped organ is located within the true pelvis, between the bladder and the rectum. The uterus is made up of the body and the cervix.

The upper segment of the uterine body, between the insertion sites of the fallopian tubes, is referred to as the *fundus*. Although the uterus is a hollow organ, its walls are in such close proximity in the nonpregnant state that its cavity is merely a slit.

The **cervix** is a short (1 inch [2.5 cm]), narrowed portion of the uterus and extends into the vagina. The surface of the cervix and the canal are the sites for Papanicolaou (Pap) testing. (See discussion on p. 1581.)

The **fallopian tubes** (uterine tubes) insert into the fundus of the uterus and extend laterally close to the ovaries. They provide a duct between the ovaries and the uterus for the passage of ova and sperm. In most cases, the ovum is fertilized in these tubes.

The **ovaries** are a pair of almond-shaped organs located near the lateral walls of the upper pelvic cavity. After menopause, they become smaller. These small organs develop and release ova and produce the sex steroid hormones (estrogen, progesterone, androgen, and relaxin). Adequate amounts of these hormones are needed for normal female growth and development and to maintain a pregnancy.

Breasts

The female **breasts** are a pair of mammary glands that develop in response to secretions from the hypothalamus, pituitary gland, and ovaries. The breasts are an accessory of the reproductive system that nourish the infant after birth.

Breast tissue is composed of a network of glandular and ductal tissue, fibrous tissue, and fat. The proportion of each component of breast tissue depends on genetic factors, nutrition, age, and obstetric history. The breasts are supported by ligaments that are attached to underlying muscles. They have abundant blood supply and lymph flow that drains from an extensive network toward the axilla (Fig. 72-2).

Structure and Function of the Male Reproductive System

The male reproductive system also consists of external and internal genitalia. The primary male hormone for sexual development and function is testosterone. Testosterone production is fairly constant in the adult male. Only a slight and gradual reduction of testosterone production occurs in the older adult male until he is in his 80s. Low testosterone levels decrease muscle mass, reduce skin elasticity, and lead to postural changes and changes in sexual performance.

The **penis** is an organ for urination and intercourse consisting of the body or shaft and the glans penis (the distal end

FIG. 72-2 Lymphatic drainage of the female breast.

of the penis). The glans is the smooth end of the penis and contains the slitlike opening of the urethral meatus. The urethra is the pathway for the exit of both urine and semen. A continuation of skin covers the glans and folds to form the prepuce (foreskin). Surgical removal of the foreskin (**circumcision**) for religious or cultural reasons is a common procedure in the United States and other Western countries.

The **scrotum** is a thin-walled, fibromuscular pouch that is behind the penis and suspended below the pubic bone. This pouch protects the testes, epididymis, and vas deferens in a space that is slightly cooler than inside the abdominal cavity.

The scrotal skin is darkly pigmented and contains sweat glands, sebaceous glands, and few hair follicles. It contracts with cold, exercise, tactile stimulation, and sexual excitement.

The internal male genitalia are shown in Fig. 72-3. The major organs are the testes and prostate gland. The testes are a pair of oval organs in the scrotum that produce sperm and testosterone. Each testis is suspended in the scrotum by the spermatic cord, which provides blood, lymphatic, and nerve supply to the testis. Sympathetic nerve fibers are located on the arteries in the cord, and sympathetic and parasympathetic fibers are on the vas deferens. When the testes are damaged, these autonomic nerve fibers transmit excruciating pain and a sensation of nausea.

The **epididymis** is the first portion of a ductal system that transports sperm from the testes to the urethra and is a site of sperm maturation. The **vas deferens**, or ductus deferens, is a firm, muscular tube that continues from the tail of each epididymis. The end of each vas deferens is a reservoir for sperm and tubular fluids. They merge with ducts from the seminal vesicle to form the ejaculatory ducts at the base of the prostate gland. Sperm from the vas deferens and secretions from the seminal vesicles move through the ejaculatory duct to mix with prostatic fluids in the prostatic urethra.

The **prostate gland** is a large accessory gland of the male reproductive system. It secretes a milky alkaline fluid that adds bulk to the semen, enhances sperm movement, and neutralizes acidic vaginal secretions. The prostate gland can

FIG. 72-3 Internal male genitalia.

be palpated through the rectum and should not project more than $\frac{3}{8}$ inch (1 cm) into the rectal lumen.

As men age, the prostate gland becomes clinically significant. Men older than 50 years commonly have an enlarged prostate (benign prostatic hyperplasia [BPH]), which can cause problems such as overflow incontinence and nocturia (nighttime urination). Prostate function depends on adequate levels of testosterone.

The inguinal area (groin) is located between the superior iliac spine and the symphysis pubis and is the junction of the lower abdominal wall and thigh. The area is a common site for a **hernia**, which is a loop of bowel that protrudes through a weak spot in the muscles.

REPRODUCTIVE CHANGES ASSOCIATED WITH AGING

Age affects the function of both the male and the female reproductive systems. Many changes in the reproductive system occur as people age (Chart 72-1).

ASSESSMENT METHODS

Patient History

Establish a trusting relationship with the patient. Many patients are hesitant to share their reproductive history or concerns about sexuality. Respect their choice to refuse to answer questions and talk about their reproductive problems or sexual practices. Chart 72-2 describes questions to consider when assessing the patient's sexuality and reproductive health using Gordon's Functional Health Patterns.

Assess the patient's health habits, such as diet, sleep, and exercise patterns. Low levels of body fat may be related to ovarian dysfunction. Assess for alcohol, tobacco, and drug use (prescribed, over-the-counter [OTC], and illicit drugs),

because **libido** (sex drive), sperm production, and the ability to have or sustain an erection can be affected by these substances.

Ask female patients about the date and result of their most recent Pap test, breast self-examination, and vulvar self-examination. Determine when male patients older than 50 years had their last prostate examination and prostate-specific antigen test.

Ask about childhood illnesses that could have an effect on the reproductive system. For example, mumps in men may cause **orchitis** (painful inflammation and swelling of the testes) and can lead to testicular atrophy and sterility.

Assess for any chronic illnesses or surgeries that could affect reproductive function. For instance, endocrine disorders may affect the hypothalamic-pituitary-gonadal function of men or women. Almost any disease that disturbs a woman's metabolism or nutrition can depress ovarian function and cause **amenorrhea** (absence of menses). Failure of ovulation is associated with a greater risk for endometrial cancer. Patients with diabetes mellitus may experience physiologic changes such as vaginal dryness or impotence. Chronic disorders of the nervous system, respiratory system, or cardiovascular system can alter the sexual response.

Reproductive system dysfunction can also result from irradiation; prolonged use of corticosteroids, internal or external estrogen, or testosterone; and chemotherapy drugs. In addition, past severe infections can alter a person's reproductive ability. For example, pelvic inflammatory disease or a ruptured appendix followed by peritonitis can cause strictures or adhesions in the fallopian tubes and pelvic scarring. **Salpingitis** (uterine tube infection) is usually caused by chlamydial infection and can result in female infertility. If a young woman began having intercourse at a very early age and/or has multiple sex partners, she is at high risk for cervical cancer. Breast cancer is more common in women who have

CHART 72-1 NURSING FOCUS ON THE OLDER ADULT

Changes in the Reproductive System Related to Aging

PHYSIOLOGIC CHANGE	NURSING INTERVENTIONS	RATIONALES
Women		
Graying and thinning of the pubic hair Decreased size of the labia majora and clitoris	Discuss changes with the patient (applies to all structures for both women and men).	Education helps prevent problems with body image (applies to all structures for both women and men).
Drying, smoothing, and thinning of the vaginal walls	Provide information about vaginal estrogen therapy and water-soluble lubricants.	Education enables the patient to make informed decisions about the treatment of vaginal dryness, which can cause painful intercourse.
Decreased size of the uterus Atrophy of the endometrium Decreased size and marked convolution of the ovaries Loss of tone and elasticity of the pelvic ligaments and connective tissue	Provide information about Kegel exercises to strengthen pelvic muscles. Urinary incontinence can be a major problem.	Strengthening exercises may prevent or reduce pelvic relaxation and urinary incontinence.
Increased flabbiness and fibrosis of the breasts, which hang lower on the chest wall; decreased erection of the nipples	Teach or reinforce the importance of breast self-awareness, clinical breast examinations, and mammography.	These methods can detect masses or other changes that may indicate the presence of cancer.
Men		
Graying and thinning of the pubic hair Increased drooping of the scrotum and loss of rugae	Teach or reinforce the importance of testicular self-examination (TSE).	TSE may detect changes that may indicate cancer.
Prostate enlargement, with an increased likelihood of urethral obstruction	Teach the patient the signs of urethral obstruction and the importance of prostate cancer screening.	Education helps the patient detect enlargement or obstruction, which may indicate the presence of cancer.

not experienced childbearing. Ask about a history of infections or prolonged fever in males that may have damaged sperm production or caused obstruction of the seminal tract, because these changes cause infertility.

Data about sexual activity are important to obtain as part of the history. Heterosexual activity should not be assumed. Lesbian, gay, bisexual, and transgender (LGBT) issues are often not assessed by health care professionals or shared by the patient. [Table 4-3 in Chapter 4](#) suggests sensitive ways to ask questions about sexual activity.

**CULTURAL AWARENESS**

Other cultural beliefs and practices influence lifestyle and sexual activity. For example, a person's religious beliefs often influence specific sexual practices, the acceptable number of sexual partners, and contraceptive use. Be sensitive to these differences by being nonjudgmental and showing acceptance.

Nutrition History

A nutrition history is often critical for an accurate assessment of reproductive system problems. For example, fatigue and low libido may occur with poor diet and anemia. Obesity raises the risk for uterine cancer. High-fat diets may increase the risk for cancer of the breast, ovary, and prostate gland ([American Cancer Society \[ACS\], 2010](#)). Ask the patient to recall his or her dietary intake for a recent 24-hour period to assess quality.

Assess the patient's height, weight, and body mass index. The patient may be hesitant to discuss practices such as bingeing, purging, anorexic behaviors, or excessive exercise. However, these practices may affect the reproductive system. A certain level of body fat and weight is necessary for the

onset of menses and the maintenance of regular menstrual cycles. Decreased body fat results in insufficient estrogen levels.

Women have special nutrition needs. Those who use oral contraceptives need increased sources of folic acid and vitamins B₆, B₁₂, and C. Heavy menstrual bleeding, particularly in women who have intrauterine devices, may require oral iron supplements. Teach all women of any age about their body's need for calcium. Although adequate calcium intake throughout life is needed, it is especially important during and after menopause to help prevent osteoporosis due to decreased estrogen production (see [Chapter 53](#)).

Family History and Genetic Risk

The family history helps determine the patient's risk for conditions that affect reproductive functioning. A delayed or early development of secondary sex characteristics may be a familial pattern.

The current age and health status of family members are important. Evidence of medical diseases or reproductive problems in family members (e.g., diabetes, endometriosis, reproductive cancer) allows better interpretation of the patient's current symptoms. For example, daughters of women who were given diethylstilbestrol (DES) to control bleeding during pregnancy are at increased risk for infertility and reproductive tract cancer.

Specific *BRCA1* and *BRCA2* gene mutations increase the overall risk for breast or ovarian cancer ([ACS, 2010](#)). Men with first-degree relatives (e.g., father, brother) with prostate cancer are at greater risk for the disease than men in the general population. Testicular cancer can also be familial ([ACS, 2010](#)). More information about genetic risks is discussed with specific health problems in later chapters of this unit.

CHART 72-2 REPRODUCTIVE ASSESSMENT

Using Gordon's Functional Health Patterns

Health Perception/Health Management Pattern

- Has anyone in your family had cancer of the breast or reproductive organs? Who and what type of cancer?
- If you engage in sexual activities, do you practice "safer" sex?
- What do you do to keep healthy—regular health checkups, self-examination (breast, genital [vulvar, testicular]), healthy diet, exercise, use of medications or alternative therapies?

Sexuality-Reproductive Pattern

Male and Female

- Are you sexually active? Do you find your sexual relationship satisfying? Have there been any changes in your relationship? Are you having any problems in your sexual relationship?
- Do you use contraceptives? If so, do you have any problems with the method of contraception?
- Have you had any sexually transmitted diseases? If yes, when and what type did you have?

Female

- When did you first start menstruating? When was your last menstrual period? Do you have any menstrual problems?
- Have you ever been pregnant? If so, how many times and what were the outcomes?
- Have you had any symptoms of menopause?

Male

- Do you have any problems with getting and maintaining an erection, or do you have difficulty with ejaculation?
- Have you ever had a hernia or pain in the groin?

Self-Perception/Self-Concept Pattern

- How would you describe yourself? Do you feel good or not so good about yourself?
- Have you experienced changes in your body appearance or function? If so, are these problematic for you? Have you felt anxious, fearful, or depressed about these changes?

Based on Gordon, M. (2011). *Manual of nursing diagnosis* (12th ed.). New York: Jones & Bartlett.

Current Health Problems

Most patients seek medical attention as a result of pain, bleeding, discharge, and masses (Chart 72-3). Pain related to reproductive system disorders may be confused with or cause signs and symptoms that are usually associated with GI or urinary health problems (e.g., urinary frequency). Ask the patient to describe the nature of the pain, including its type, intensity, timing and location, duration, and relationship to menstrual, sexual, urinary, or GI function. Assess the factors that **exacerbate** (worsen) or relieve the pain. Ask about sleeping patterns and if pain or other manifestation is affecting the ability to get adequate rest (Ruhl, 2010).

Heavy *bleeding* or a lack of bleeding may concern the patient. Consider the possibility of pregnancy in any sexually active woman with amenorrhea. Any postmenopausal bleeding needs to be evaluated. Ask the patient to describe the amount and character of abnormal vaginal or penile bleeding. Assess whether the bleeding occurs in relation to the menstrual cycle or menopause, intercourse, trauma, or strenuous exercise. Ask about any associated symptoms, such as pain, cramping or abdominal fullness, a change in bowel habits, urinary difficulties, and weight changes. Many factors

CHART 72-3 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Assessing the Patient with Reproductive Health Problems

PATIENT CONCERN

NURSING ASSESSMENT

Pain	Type and intensity of pain Location and duration of pain Factors that relieve or worsen pain Relationship to menstrual, sexual, urinary, or GI function Medications
Bleeding	Presence or absence of bleeding Character and amount of bleeding Relationship of bleeding to events or other factors (e.g., menstrual cycle) Onset and duration of bleeding Presence of associated symptoms, such as pain
Discharge	Amount and character of discharge Presence of genital lesions, bleeding, itching, or pain Presence of symptoms or discharge in sexual partner
Masses	Location and characteristics of mass Presence of associated symptoms, such as pain Relationship to menstrual cycle

can cause bleeding, and sites other than the genital tract need to be considered.

Discharge from either the male or female reproductive tract can cause severe irritation of the surrounding tissues, itching, pain, embarrassment, and anxiety. Ask about the amount, color, consistency, odor, and chronicity of the discharge. Drugs (e.g., antibiotics) and clothing (e.g., tight jeans, synthetic underwear fabric) may cause or worsen genital discharge. Many types of discharge are caused by sexually transmitted diseases (STDs) (see Chapter 76). The body location of these infections may depend on the patient's sexual practices. Ask the patient about lesions, bleeding, itching, and pain related to the genitals and orifices used during sexual activity. Also inquire about the presence of symptoms in the sexual partner(s).

Any reported *masses* in the breasts, testes, or inguinal area are evaluated. Some masses change in character or size. The patient can often relate these changes to menstrual cycles, heavy lifting, straining, or trauma. Ask about associated symptoms such as tenderness, heaviness, pain, dimpling, and tender lymph nodes.

Physical Assessment

Assessment of the Female Reproductive System

The medical-surgical nurse does not perform a comprehensive female or male reproductive examination. However, perform a focused assessment for specific concerns of the patient. The physician or advanced practice nurse does a more thorough gynecologic assessment as described below. The medical-surgical nurse often assists with the examination.

The physical examination of the reproductive system usually includes the breasts (see Chapter 73). After the breast examination, the examiner generally completes the thoracic and cardiovascular examinations and then inspects, auscultates, and palpates the abdomen. The patient's arms should be at her sides or over her chest to allow better relaxation of

the abdominal muscles. During the gynecologic examination, the examiner palpates for symptomatic and asymptomatic abdominopelvic masses. A mass can be of reproductive, intestinal, or urinary tract origin. Careful history-taking combined with the physical examination can usually determine the origin of a mass. Gynecologic masses, such as ovarian masses, may be further differentiated from lesions on the body of the uterus during the bimanual portion of the pelvic examination.

Inspection of the female genitalia and the pelvic examination are usually performed at the end of a head-to-toe physical assessment. The patient is often more apprehensive about these portions of the examination than about any other part. Pain or lack of privacy during previous pelvic or breast examinations may prevent the patient from relaxing.

Other than determining pregnancy or infertility, a pelvic examination is indicated to assess for:

- Menstrual irregularities
- Unexplained abdominal or vaginal pain
- Vaginal discharge, itching, sores, or infection
- Rape trauma or other pelvic injury
- Physical changes in the vagina, cervix, and uterus

Immediately before the pelvic and breast examinations, ask the patient to empty her bladder and undress completely. Drape the woman adequately to protect modesty throughout the examination. If she is not wearing a gown, a small towel can be placed over the breasts under the larger drape. Remove drapes only over the region being examined, and replace them after that area has been assessed. Drapes that prevent eye contact between the examiner and the patient are dehumanizing and prevent comfort during the examination. Mirrors can be used to facilitate teaching if the patient so desires. The examination is performed in a room that has adequate lighting for body inspection, that is a comfortable temperature, and that ensures privacy.

Assessment of the Male Reproductive System

Unless a male patient seeks health care for specific problem, the examiner may not inspect and palpate the male genitalia and rectum during physical examinations, depending on the health care setting and the age of the patient. Men are often embarrassed and anxious when the reproductive system is assessed. This concern may be worse when the examiner is a woman. The patient may be concerned about discomfort, the developmental stage of his genitalia, or the likelihood of an erection during the examination. If he does have an erection, the examiner should assure him that this is a normal response to a tactile stimulus (touch) and should continue the examination.

As with examinations of other body systems, explain each step of the assessment procedure before it is performed. The patient needs to be reassured that the examiner will stop and change the assessment plan or technique if the patient has pain during the examination. Teach relaxation techniques and provide support during the examination to increase comfort.

Psychosocial Assessment

The psychosocial assessment may suggest factors that lead to the patient's health problem. During the social history, ask about sources of support, strengths, and likely reactions to illness or dysfunction.

A patient's personal history or beliefs may negatively influence his or her ability to enjoy a satisfactory sexual life. These factors may include:

- Sexual trauma or abuse inflicted during childhood or adulthood
- Punishment for masturbation
- Psychological trauma
- Cultural influences, such as the idea of female passivity during intercourse
- Concerns about sexual partners or sexual lifestyle
- Use of alcohol or street drugs

Fears may affect the patient's satisfaction with sexuality or body image. He or she may also be concerned about the potential or actual reaction of family members to reproductive health problems (see [Chart 72-2](#)).

Diagnostic Assessment

Laboratory Assessment

The **Papanicolaou test**, or **Pap smear**, is a cytologic study that is effective in detecting precancerous and cancerous cells from the cervix. It is done immediately before the pelvic examination. A speculum is inserted into the vagina, and several samples of cells from the cervix are obtained with a small brush or spatula. The specimens are placed on a glass slide and sent to the laboratory for examination.

The Pap test should be scheduled between the woman's menstrual periods so that the menstrual flow does not interfere with the test interpretation. Teach women not to douche, use vaginal medications or deodorants, or have sexual intercourse for at least 24 hours before the test.

Based on current evidence, the American Cancer Society (ACS) advises all women to begin having an annual Pap test within 3 years of becoming sexually active or by no later than 21 years of age. Annual screening is recommended until 30 years of age with the conventional Pap test or every 2 years if a liquid-based test is used. After age 30 and three or more consecutive normal test results, Pap tests may be performed every 3 years until 70 years of age. Women 70 years and older who have had normal results for 10 consecutive years may discontinue testing. Those who have had a total hysterectomy, including the cervix, do not need Pap smear testing. Women who have the surgery but still have their cervix should follow the guidelines for other women (ACS, 2011).

Cytologic vaginal *cultures* can detect bacterial, viral, fungal, and parasitic disorders. Examination of cells from the vaginal walls can evaluate estrogen balance.

The **human papilloma virus (HPV) test** can identify many high-risk types of HPV associated with the development of cervical cancer. This test can be done at the same time as the Pap test for women older than 30 years and for women of any age who have had an abnormal Pap test result. It does not take the place of the Pap test because it tests for the viruses that can cause cell changes in the cervix that, if not treated, could lead to cancer. Cells are collected from the cervix and sent to a laboratory for analysis. Women who have normal Pap test results and no HPV infection are at very low risk for developing cervical cancer. Conversely, women with an abnormal Pap result and a positive HPV test are at higher risk if not treated.

Serum levels of follicle-stimulating hormone (FSH), luteinizing hormone (LH), and prolactin are helpful in the

TEST	NORMAL RANGE FOR ADULTS	SIGNIFICANCE OF ABNORMAL FINDINGS
Serum Studies		
Follicle-stimulating hormone (FSH) (Folliotropin)	Men: 1.42-15.4 IU/L Women: follicular phase, 1.37-9.9 IU/L; midcycle, 6.17-17.2 IU/L; luteal phase, 1.09-9.2 IU/L; postmenopause, 19.3-100.6 IU/L	Decreased levels indicate possible infertility, anorexia nervosa, neoplasm. Elevations indicate possible Turner's syndrome.
Luteinizing hormone (LH) (Lutropin)	Men: 1.24-7.8 IU/L Women: follicular phase, 1.68-15 IU/L; midcycle, 21.9-56.6 IU/L; luteal phase, 0.61-16.3 IU/L; postmenopause, 14.2-52.3 IU/L	Decreased levels indicate possible infertility, anovulation. Elevations indicate possible ovarian failure, Turner's syndrome.
Prolactin	Men: 0-20 ng/mL Women: 0-20 ng/mL Pregnant women: 20-400 ng/mL	Elevations indicate possible galactorrhea (breast discharge), pituitary tumor, disease of hypothalamus or pituitary gland, hypothyroidism.
Estradiol	Men: 10-50 pg/mL Women: follicular phase, 20-350 pg/mL; midcycle, 150-750 pg/mL; luteal phase, 30-450 pg/mL; postmenopause, ≤20 pg/mL	Elevations of estradiol, total estrogens, and estriol in men indicate possible gynecomastia, decreased body hair, increased fat deposits, feminization, testicular tumor; in women, ovarian tumor.
Estriol	Men and nonpregnant women: <2.0 ng/dL	Decreased levels of estradiol, total estrogens, and estriol in women indicate possible amenorrhea, climacteric, impending miscarriage, hypothalamic disorders.
Progesterone	Men: 10-50 ng/dL Women: follicular phase, <50 ng/dL; luteal phase, 300-2500 ng/dL; postmenopausal, <40 ng/dL	Decreased levels in women indicate possible inadequate luteal phase, amenorrhea. Elevations in women indicate possible ovarian luteal cysts. Decreased levels may indicate ovarian neoplasm, ovarian dysfunction.
Testosterone	Men: 280-1080 ng/dL Women: <70 ng/dL	Increased levels in men indicate possible testicular tumor, hyperthyroidism. Decreased levels in men indicate possible hypogonadism. Elevations in women indicate possible adrenal neoplasm, ovarian neoplasm, polycystic ovary syndrome.
Prostate-specific antigen	Men: <4 ng/mL	Increased levels may indicate prostatitis, benign prostatic hyperplasia, prostate cancer.
Urine Studies		
Total estrogens	Men: 4-25 mcg/24 hr Women: 4-60 mcg/24 hr	Elevations indicate possible testicular tumors. Decreased levels indicate possible ovarian dysfunction.
Pregnanediol	Men: 0-1.9 mg/24 hr Women: follicular phase, <2.6 mg/24 hr; luteal phase, 2.6-10.6 mg/24 hr	Elevations indicate possible luteal ovarian cysts, ovarian neoplasms, adrenal disorders. Decreased levels indicate possible amenorrhea.
17-Ketosteroids	Men (20-50 yr): 6-20 mg/24 hr Women (20-50 yr): 6-17 mg/24 hr Values decrease with age	Elevations indicate possible Cushing's syndrome, increased androgen or cortisol production, severe stress. Decreased levels indicate possible Addison's disease, hypopituitarism.

Data from Pagana, K.D., & Pagana, T.J. (2010). *Mosby's manual of diagnostic and laboratory tests* (4th ed.). St. Louis: Mosby.
 1 mcg, 1 microgram or 1 millionth of a gram; 1 ng, 1 nanogram or 1 billionth of a gram; 1 pg, 1 picogram or 1 trillionth of a gram.

diagnosis of male and female reproductive tract disorders. No nutrition restrictions are necessary before the test. Serum testing can also detect estrogen, progesterone, and testosterone levels in men and women. [Chart 72-4](#) gives the normal values and the significance of abnormal findings.

Serologic studies detect antigen-antibody reactions that occur in response to foreign organisms. This form of diagnostic testing is helpful only after an infection has become well established. Serologic testing can be used in the evaluation of exposure to organisms causing syphilis, rubella, and herpes simplex virus type 2 (HSV2). Results may be read as nonreactive, weakly reactive, or reactive. A single titer is not as revealing as serial titers, which can detect the rise in antibody reactions as the body continues to fight the infection.

Human immune deficiency virus (HIV) testing should be offered to all patients ages 19 to 64 years, especially those with personal risk factors (see [Chapter 21](#) for a detailed discussion of HIV testing). Testing for sexually transmitted diseases should be performed if patients have signs and symptoms associated with these problems. These tests are discussed in other chapters of this unit.

The **prostate-specific antigen (PSA)** test is used to screen for prostate cancer and to monitor the disease after treatment. PSA levels less than 4 ng/mL are normal. Elevated PSA levels, especially above 10 ng/mL, are associated with prostate cancer. Older men, particularly African-American men, often have a higher normal PSA, especially as they age.

The patient should not ejaculate for at least 24 hours before the test to avoid a false-positive result. For the same

 NCLEX EXAMINATION CHALLENGE**Health Promotion and Maintenance**

A 25-year-old client asks the nurse if she needs a Pap smear. How should the nurse respond to this question?

- A. "You don't need a Pap test until you turn 30 years old."
- B. "You should have a Pap smear every year if you are sexually active."
- C. "You should have a Pap smear every 2 years as long as it is liquid-based testing."
- D. "You should ask your nurse practitioner when she sees you."

reason, the blood for the PSA test should be drawn before the digital rectal examination (Pagana & Pagana, 2010).

Imaging Assessment

General X-rays. A kidney, ureter, and bladder (KUB) x-ray of the abdomen shows these structures and is used in the assessment of disorders of either the male or the female reproductive system. Pelvic masses, calcified tumors or fibroids, dermoid cysts, and metastatic bone changes may be seen. No specific preparation is needed.

Bone scans and chest x-rays may also be included in the workup of the patient with suspected metastatic cancer. They help determine the extent of the cancer spread and obstruction or displacement of the organs. These tests are discussed elsewhere in this text.

Computed Tomography. Computed tomography (CT) scans for reproductive system disorders involve the abdomen and the pelvis. They can detect and evaluate masses and lymphatic enlargement from metastasis. This scan can differentiate solid tissue masses from cystic or hemorrhagic structures.

Hysterosalpingography. A **hysterosalpingogram** is an x-ray of the cervix, uterus, and fallopian tubes and is performed after the injection of a contrast medium. This test is used to evaluate tubal anatomy and patency and uterine problems such as fibroids, tumors, and fistulas. The study should not be attempted for at least 6 weeks after abortion, delivery, or dilation and curettage. Other contraindications include reproductive tract infection and uterine bleeding.

The examination is scheduled in a radiology department 2 to 5 days after the end of the patient's normal menses. The scheduling is important to prevent the accidental flushing of a fertilized ovum from the fallopian tube or the exposure of a fetus to radiation.

The patient is usually instructed to take a laxative the evening before the test, followed by an enema or rectal suppository on the morning of the examination. These procedures reduce the distortion of the x-rays by gas shadows.

On the day of the examination, confirm the date of the patient's last menstrual period and record it in the medical record. Ask about allergies to iodine dye or shellfish. The patient signs a consent form for the procedure. Because discomfort is expected during the examination, premedication with analgesics or NSAIDs may be prescribed. Inform the patient that she may experience some nausea and vomiting, abdominal cramping, or faintness. Provide support and assistance with relaxation techniques.

The patient is placed in the lithotomy position. A speculum is inserted, and the cervix is viewed. Dye is injected through the cervix to fill and highlight the interior of the

cervix, uterus, and fallopian tubes. If the fallopian tubes are patent, the contrast material spills into the peritoneal cavity. Usually, only two or three views are obtained to show the path and distribution of the contrast medium.

The patient may experience pelvic pain after the study and should receive analgesic drugs accordingly. She may also have referred pain to the shoulder because of irritation of the phrenic nerve. Provide a perineal pad after the test to prevent the soiling of clothes as the dye drains from the cervix. Instruct the woman to contact her health care provider if bloody discharge continues for 4 days or longer and to report any signs of infection, such as lower quadrant pain, fever, malodorous discharge, or tachycardia.

Mammography. **Mammography** is an x-ray of the soft tissue of the breast. Mammograms assess differences in the density of breast tissue. They are especially helpful in evaluating poorly defined masses, multiple masses or nodules, nipple changes or discharge, skin changes, and pain. Mammography can detect about 80% to 90% of cancers that are not palpable by physical examination. However, some actual cancers may not appear on mammography or may appear as benign (ACS, 2011).

In young women's breasts, there is little difference in the density between normal glandular tissue and malignant tumors, which makes the mammogram less useful for evaluation of breast masses in these women. For this reason, annual screening mammograms are not recommended for women younger than 40 years (ACS, 2011). In older women, the amount of fatty tissue is higher and the fatty tissue appears lighter than cancers. Cancer and cysts may have the same density. Cysts usually have smooth borders, and cancers often have starburst-shaped margins.

No dietary restrictions are necessary before the mammogram. Remind the patient not to use creams, powders, or deodorant on the breasts or underarm areas before the study because these products can show on the x-ray. If there is any possibility that the patient is pregnant, the test should be rescheduled. Explain the purpose of the examination and its anticipated discomforts. Provide a cover gown and adequate privacy to undress above the waist. The patient also needs support and may need time to express her concerns about the mammogram and the presence of any lumps.

The technician positions the woman next to the x-ray machine with one breast exposed. A film plate and the platform of the machine are placed on opposite sides of the breast to be examined. The technician includes as much breast tissue as possible between the plates. The woman may experience some temporary discomfort when the breast is compressed during the positioning and the test. The test takes about 15 minutes, but the patient is usually asked to wait until the films are developed in case a view needs to be repeated. Some facilities are now using digital imaging rather than films.

The woman should know when to expect the report of the results. Because this is a time when the woman is anxious about the health of her breasts, it is a good opportunity to teach or reinforce the importance of breast self-examination (BSE) and give instructions as needed.

Other Diagnostic Assessment

Ultrasonography. Ultrasonography (US) is a technique that is routinely used to assess problems such as uterine fibroids, ovarian cysts, and pelvic masses. It can be used to

monitor the progress of tumor regression after medical treatment. US is also helpful in differentiating solid tumors from cysts in breast examinations. In men, ultrasound can test for varicoceles, scrotal abnormalities, and problems of the ejaculatory ducts and seminal vesicles and the vas deferens (Pagana & Pagana, 2010).

No specific preparations are needed for this study. Women should have a full bladder to help view the uterus and to make the location of other structures more distinct with abdominal ultrasonography. A full bladder is not needed for breast, scrotal, transvaginal, or transrectal scans.

For an abdominal, breast, or scrotal scan, the technician exposes the area and applies oil or gel to the area to be scanned. These substances provide better transmission of sound waves from the transducer through the patient's skin. The transducer is moved in a linear pattern across the area being tested to outline and define soft-tissue masses and to differentiate tumor type, ascites, and encapsulated fluid.

For a *transvaginal* or *transrectal* scan, the transducer is covered with a condom or vinyl glove onto which transmission gel has been placed. The transducer is then inserted into the vagina or rectum as indicated.

The patient may want to watch the viewing screen with a brief explanation of the landmarks and structures seen. There is no special follow-up care for the patient after this procedure except to provide wipes to remove the gel.

Magnetic Resonance Imaging. Magnetic resonance imaging (MRI) uses a magnetic field and radiofrequency energy to scan for pelvic tumors. This scan distinguishes between normal and malignant tissues. MRIs are now being used in the diagnosis of breast cancer in women who have a genetic risk (ACS, 2011). The use of MRI in evaluating patients with dense breast tissue may reduce the need for biopsy.

Endoscopic Studies

Colposcopy. The colposcope allows three-dimensional magnification and intense illumination of epithelium with suspected disease. **Colposcopy** is suited for inspection of the cervical epithelium, vagina, and vulvar epithelium. This procedure can locate the exact site of precancerous and malignant lesions for biopsy.

The woman is placed in the lithotomy position and provided the same support as for a pelvic examination. The patient should not douche or use vaginal preparations for 24 to 48 hours before the test. This nearly painless procedure is better tolerated if it is explained in advance and if the instrument is shown to the patient.

Colposcopy provides accurate site selection for tissue biopsy. Therefore the patient should also be prepared for a biopsy. Materials for cytologic studies and biopsy should be readily available.

The physician locates the cervix or vaginal site through a speculum examination. Lubricants other than water should not be used. Cells in the area may be stained or left unstained to enhance visibility. The physician cleans and moistens the cervix with normal saline. This increases the visibility of vascular patterns and the junction between the columnar epithelium and the squamous epithelium. Acetic acid, 3%, is applied to the cervix to draw moisture from the tissue and to accentuate important features. The physician then uses a colposcope or colpomicroscope to inspect the area in question.

A biopsy specimen may also be taken if abnormal cells are seen. (See Cervical Biopsy section on p. 1585.)

After the procedure, assist the woman as you would for a pelvic examination and provide supplies to clean the perineum. Also give her a perineal pad to absorb any dye or discharge. If a biopsy specimen is taken, additional follow-up care is needed.

Laparoscopy. **Laparoscopy** is a direct examination of the pelvic cavity through an endoscope. This procedure can rule out an ectopic pregnancy, evaluate ovarian disorders and pelvic masses, and aid in the diagnosis of infertility and unexplained pelvic pain. Laparoscopy is also used during surgical procedures such as:

- Tubal sterilization
- Ovarian biopsy
- Cyst aspiration
- Removal of endometriosis tissue
- Lysis of adhesions around the fallopian tubes
- Retrieval of “lost” intrauterine devices

A laparoscopy is used instead of a laparotomy for minor surgical procedures because it uses small incisions, involves less discomfort, and does not require overnight hospitalization.

Patient Preparation. The physician explains the procedure, risks (complications associated with the use of general anesthesia, postoperative shoulder pain, and the rare occurrence of infection or electrical burns), and anticipated discomforts and obtains the patient's consent. The procedure can be performed with either a regional or general anesthetic. Patients should expect mild discomfort from the incision site and may experience referred shoulder pain from phrenic nerve irritation.

Procedure. The patient is anesthetized and placed in the lithotomy position. A urinary catheter is inserted to drain the bladder. The operating table is placed in a slight Trendelenburg position to cause the intestines to fall away from the pelvis. The cervix is held with a cannula to allow movement of the uterus during laparoscopy (Fig. 72-4). The surgeon

FIG. 72-4 Laparoscopy. CO₂, Carbon dioxide.

inserts a needle below the umbilicus to infuse carbon dioxide (CO₂) into the pelvic cavity, which distends the abdomen and permits better visualization of the organs. After the trocar and cannula are in place in the abdominal cavity, the surgeon removes the trocar and inserts the laparoscope. The surgeon can then visualize the pelvic cavity and reproductive organs. Further instrumentation is possible through one or more small incisions. The laparoscope is removed at the end of the procedure, and the abdomen is deflated. The small incision is closed with absorbable sutures and dressed with an adhesive bandage.

Follow-up Care. Care after surgery is similar to that for other patients after general anesthesia. The patient is usually discharged on the day of the procedure. Discomfort from the incision is managed by oral analgesics. The greatest discomfort is due to referred shoulder pain caused by residual CO₂ in the peritoneal cavity. Most of these sensations disappear within 48 hours. Instruct the patient to change the small adhesive bandage as needed and to observe the incision for signs of infection or hematoma. Remind her to avoid strenuous activity for the first week after the procedure.

Hysteroscopy. **Hysteroscopy** is an endoscopic examination to view the interior of the uterus and the cervical canal. The hysteroscope includes a fiberoptic camera. Aqueous carbon dioxide is the medium used to distend the uterus. Hysteroscopy can be used for the removal of intrauterine devices and as a complement to other diagnostic tests for infertility and unexplained bleeding.

The surgeon informs the patient of all aspects of the procedure and obtains consent. The preparation is the same as for a pelvic examination. The procedure is best performed 5 days after menses has ceased to reduce the possibility of pregnancy. The woman is placed in the lithotomy position and is usually anesthetized with a paracervical or other regional block.

After she is anesthetized, the cervix is dilated. The physician inserts the hysteroscope through the cervix. Because a medium distends the uterus, cells can be pushed through the fallopian tubes and into the pelvic cavity. Therefore hysteroscopy is contraindicated in patients with suspected cervical or endometrial cancer, in those with infection of the reproductive tract, and in pregnant patients.

Care is the same as that after a pelvic examination. Analgesics may be prescribed if the patient has cramping or shoulder pain.

Biopsy Studies

Cervical Biopsy. In a cervical biopsy, cervical tissue is removed for cytologic study. A biopsy is indicated for an identifiable cervical lesion, regardless of the cytologic findings. The health care provider usually performs a biopsy in conjunction with colposcopy as a follow-up to a suspicious Pap test finding. The procedure may be performed in a clinic or office setting.

Several techniques can be used for a cervical biopsy. If a lesion is clearly visible, an endocervical curettage can be performed as an ambulatory care procedure and with little or no anesthetic. **Conization** (removal of a cone-shaped sample of tissue) and loop electrosurgical excision procedures (LEEPs) are usually not done unless the cervical biopsy findings are positive or the results of the colposcopy are unsatisfactory (Lowdermilk & Perry, 2011). Conization can be done as a

CHART 72-5 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

The Patient Recovering from Cervical Biopsy

- Do not lift any heavy objects until the site is healed (about 2 weeks).
- Rest for 24 hours after the procedure.
- Report any excessive bleeding (more than that of a normal menstrual period) to your health care provider.
- Report signs of infection (fever, increased pain, foul-smelling drainage) to your health care provider.
- Do not douche, use tampons, or have vaginal intercourse until the site is healed (about 2 weeks).
- Keep the perineum clean and dry by using antiseptic solution rinses (as directed by your health care provider) and changing pads frequently.

cold-knife procedure, a laser excision, or an electrosurgical incision.

The biopsy is usually scheduled when the woman is in the early proliferative phase of the menstrual cycle, when the cervix is least vascular. Because a biopsy evaluates potentially cancerous cells, most women are anxious and need time to discuss their feelings and fears. The use of relaxation techniques may assist comfort. Assist the patient into the lithotomy position and prepare her in the same way as for a pelvic examination. Further preparation depends on the type of procedure to be performed.

The physician may anesthetize the patient according to the needs of the chosen procedure. He or she visualizes the cervix and obtains the tissue sample. All specimens are immediately placed into a formalin solution.

The type of anesthetic used for the procedure determines the type of immediate care needed after the procedure. Discharge instructions are listed in [Chart 72-5](#).

Endometrial Biopsy. Both endometrial biopsy and aspiration are used to obtain cells directly from the lining of the uterus to assess for cancer of the endometrium. Biopsy also helps assess menstrual disturbances (especially heavy bleeding) and infertility (corpus luteum dysfunction).

When menstrual disturbances are being evaluated, the biopsy is generally done in the immediate premenstrual period to provide an index of progesterone influence and ovulation. A biopsy performed in the second half of the menstrual cycle (about days 21 and 22) evaluates corpus luteum function and the presence or absence of a persistent secretory endometrium. Postmenopausal women may undergo biopsies at any time.

Menstrual data are obtained from the patient and are included on the specimen request for the pathologist. The woman has the same preparation as for a pelvic examination. Advise her that she may experience some cramping when the cervix is dilated. Analgesia before the procedure and relaxation and breathing techniques during the procedure may be helpful.

An endometrial biopsy is usually done as an office procedure with or without anesthesia. After the uterus is measured and the cervix dilated, the physician inserts the curette or intrauterine cannula into the uterus. A portion of the endometrium is withdrawn using either the cuplike end of the curette or with suction equipment. The patient usually has

moderate cramping. The specimens are placed into a formalin solution and sent for histologic examination.

Allow the woman to rest on the examining table until the cramping has subsided. Provide a perineal pad and a wipe to clean the perineum. Tell her that spotting may be present for 1 to 2 days but any signs of infection or excessive bleeding should be reported to the physician. Instruct the patient to avoid intercourse or douching until all discharge has ceased. Results of the biopsy are usually available within 72 hours.

Breast Biopsy. All breast masses should be evaluated for the possibility of cancer in women or, far less often, in men. Fibrocystic lesions, fibroadenomas, and intraductal papillomas can be differentiated by biopsy. Any discharge from the breasts is examined histologically.

The instructions to the patient depend on the type of biopsy and the type of anesthesia. Explain the procedure. Most biopsies are performed in an ambulatory care setting. Several methods are used to biopsy breast tissue. The patient usually receives a local anesthetic, and the tissue either is aspirated through a large-bore needle (core-needle biopsy) or is removed using a small incision to extract multiple samples of tissue.

Aspirated fluid from benign cysts may appear clear to dark green–brown. Bloody fluid suggests cancer. The specimens also undergo histologic evaluation. If cancer is found, the tissue is evaluated for estrogen receptor analysis. [Chapter 73](#) discusses types of breast cancer and their relationship to estrogen receptors.

NCLEX EXAMINATION CHALLENGE

Physiological Integrity

A client has a left needle breast biopsy with local anesthesia. What post-test teaching will the nurse provide?

- A. "Do not use your left arm for at least a week."
- B. "You'll likely have some discomfort for about a week."
- C. "Do not lift anything over 10 pounds for a week."
- D. "Remember to take all of your antibiotics as prescribed."

Discomfort after surgery is usually mild and is controlled with analgesics or the use of ice or heat, depending on the type and extent of the biopsy. Teach the patient how to assess the area or incision for bleeding and edema. Tell women to wear a properly supportive bra continuously for 1 week after surgery. Numbness around the biopsy site may last several weeks. If cancer is identified, provide emotional support as well as information about follow-up treatment alternatives.

Prostate Biopsy. When prostate cancer is suspected, the physician performs a needle aspiration biopsy of the prostate gland for histologic study. This procedure is often performed at the same time as cystoscopy, when the patient is under moderate sedation. The physician can perform needle biopsies without anesthesia or with the patient under local anesthesia.

Preparation for the procedure depends on the technique used to puncture the gland. Explain about the expected discomforts. Teach the patient about breathing and relaxation techniques for use during the examination. Because the purpose of this procedure is to evaluate prostate cells for cancer, the man needs support and time to discuss his fears. Preparation for a transrectal biopsy involves the use of cleansing enemas. Prophylactic antibiotics are given to reduce the risk for bacterial contamination of the blood or prostate tissue. Local anesthesia is used for transperineal biopsy.

The patient is placed in the same position as for a rectal examination. After injecting a local anesthetic for the transperineal biopsy, the physician places a finger in the rectum to help guide the needle to the prostate. For the transrectal biopsy, the physician places the needle against the examining finger and then inserts it into the rectum to the prostate. From this site, the needle is advanced through the rectal mucosa and into the prostate gland. The aspiration may be repeated several times to obtain a satisfactory specimen.

Although not common, sepsis is a life-threatening complication of transrectal biopsy. Teach the patient to report any manifestations of infection (e.g., fever, low back pain). Prophylactic antibiotics may be prescribed.

NURSING CONCEPT REVIEW

What should you expect to see in a patient without reproductive health problems that affect sexuality?

Physical assessment

- No vaginal bleeding other than usual menstruation
- No unusual vaginal discharge
- No penile bleeding or discharge
- No masses or lesions on internal or external genitalia for men or women
- Reports ability to have intercourse without pain

Psychosocial assessment

- Reports satisfaction with sexual activity
- Reports satisfaction with body image

Laboratory assessment

- Sex hormones within normal limits for age
- Prostate-specific antigen within normal limits for age

GET READY FOR THE NCLEX® EXAMINATION!**KEY POINTS**

Review these Key Points for each NCLEX Examination Client Needs Category.

Health Promotion and Maintenance

- Encourage all women to follow recommended Pap screening guidelines for early detection of precancerous and cancerous cells from the cervix.
- Assess cultural issues when identifying risks for certain reproductive problems and when evaluating health promotion practices.
- Explain all diagnostic procedures, restrictions, and follow-up care to the patient scheduled for tests.

Psychosocial Integrity

- Allow the patient the opportunity to express fear or anxiety regarding tests of the reproductive system or regarding a potential change in sexual or reproductive function.
- Assess the patient's level of comfort in discussing issues related to reproduction and sexuality.

- Encourage patients to express feelings of anxiety or discomfort related to genital examinations.

Physiological Integrity

- Urge patients with pain, bleeding, discharge, masses, or changes in reproductive function to seek health care advice.
- Provide as much privacy as possible for patients undergoing examination or testing of the reproductive system.
- Recall that reproductive changes occur with aging, as described in [Chart 72-1](#).
- Selected laboratory tests used for diagnosing reproductive health problems are found in [Chart 72-4](#).
- Teach women to report manifestations of infection to their health care provider after endoscopic procedures and biopsies of the breast, cervix, and endometrium.
- Instruct men to report manifestations of infection to their health care provider after a transrectal biopsy of the prostate.

Care of Patients with Breast Disorders

LEARNING OUTCOMES

Safe and Effective Care Environment

1. Identify community resources for patients with breast cancer.

Health Promotion and Maintenance

2. Describe the three-pronged approach to early detection of breast masses: mammography, clinical breast examination (CBE), and breast self-awareness.
3. Teach a woman who chooses breast self-examination (BSE) as an option to use correct technique.
4. Explain the options available to a person at high genetic risk for breast cancer.
5. Evaluate patient risk factors for breast cancer.

Psychosocial Integrity

6. Explain the psychosocial aspects related to having breast cancer and undergoing treatments for breast cancer.
7. Discuss sexuality issues with the patient having breast surgery.

8. Describe body image changes that can result from breast cancer surgery.

Physiological Integrity

9. Compare assessment findings associated with benign breast lesions with those of malignant breast lesions.
10. Explain the difference between breast reduction and breast augmentation.
11. Discuss treatment options for breast cancer.
12. Develop a postoperative collaborative plan of care for a patient with breast cancer.
13. Describe the role of radiation and drug therapy in the care of patients with breast cancer.
14. Identify the role of complementary and alternative therapies in breast cancer management.
15. Explain what options are available to a woman considering breast reconstruction.

Breast disorders may be benign or cancerous. Western society places a great emphasis on the breast as part of feminine beauty. Any threat to the breast has a significant effect on a woman's self-image and *sexuality*. She may feel unattractive to her partner and worry that their relationship will be negatively affected. She may be embarrassed at how she looks after treatment and refuse to look at herself. Members of the health care team need to be very supportive and acknowledge these feelings and concerns about the woman's perceived

inability to meet her need for *sexuality*. When caring for patients with breast problems, provide privacy and protect their dignity.

BENIGN BREAST DISORDERS

Most breast lumps are benign. Because the incidence of breast disease is related to age, breast disorders are described below in an age-related order (Table 73-1).

TABLE 73-1 TYPICAL PRESENTATION OF BENIGN BREAST DISORDERS

BREAST DISORDER	DESCRIPTION	INCIDENCE
Fibroadenoma	Most common benign lesion; solid mass of connective tissue that is unattached to the surrounding tissue	During teenage years into the 30s (most commonly)
Fibrocystic breast condition	<i>First stage:</i> Characterized by premenstrual bilateral fullness and tenderness <i>Second stage:</i> Presence of bilateral multi-centric nodules <i>Third stage:</i> Presence of microscopic and macroscopic cysts	Late teens and 20s
Ductal ectasia	Hard, irregular mass or masses with nipple discharge, enlarged axillary nodes, redness, and edema; difficult to distinguish from cancer	Women approaching menopause
Intraductal papilloma	Mass in duct that results in nipple discharge; mass is usually not palpable	Women 40 to 55 yr of age

FIBROADENOMA

Fibroadenomas are the most common benign tumor in women during the reproductive years. However, they also may occur in a few postmenopausal women. A **fibroadenoma** is a mass of connective tissue that is unattached to the surrounding breast tissue and is usually discovered by the woman herself or during mammography. Although the immediate fear is that of breast cancer, the risk for it occurring within a fibroadenoma is very small. On clinical examination, the tumors are oval, freely mobile, and rubbery. Their size varies from smaller than 1 cm (0.4 inch) in diameter to as large as 15 cm (6 inches) in diameter.

Fibroadenomas may occur anywhere in the breast. The health care provider may request a breast ultrasound examination or may perform a needle aspiration to establish whether the lump is cystic (fluid-filled) or solid. If the lesion is solid, ambulatory care excision using local anesthesia is sometimes the treatment of choice.

FIBROCYSTIC BREAST CONDITION

Pathophysiology

Fibrocystic changes of the breast include a range of changes involving the lobules, ducts, and stromal tissues of the breast. Because these changes affect at least half of women over the life span, they are referred to as **fibrocystic breast condition (FBC)** rather than fibrocystic disease. This condition most often occurs in premenopausal women between 20 and 50 years of age and is thought to be caused by an imbalance in the normal estrogen-to-progesterone ratio. Typical symptoms include breast pain and tender lumps or areas of thickening in the breasts. The lumps are rubbery, ill defined, and commonly found in the upper outer quadrant of the breast (Lee, 2009).

The two main features of FBC are fibrosis and cysts. Areas of fibrosis are made up of fibrous connective tissue and are

firm or hard. Cysts are spaces filled with fluid lined by breast glandular cells. Microcysts are small, nonpalpable cysts inside the breast glands. Macrocysts occur when fluid continues to build up. They often enlarge in response to monthly hormonal changes, stretching the surrounding breast tissue, and become painful. Symptoms usually resolve after menstruation and then recur before the next menstrual period in a cyclic fashion. Breast ultrasound is used to confirm the presence of a cyst. Fine needle aspiration is used to drain the cyst fluid and reduce pressure and pain. Fluid may return, and more aspirations may be necessary.

Postmenopausal women taking hormone replacement therapy (HRT) may develop FBC or experience worsening of symptoms. Having cysts or fibrosis does not increase a woman's chance of developing breast cancer. However, if a lump is very firm or has other features raising the concern about cancer, mammography is indicated. A needle biopsy or a surgical biopsy may be needed to make sure cancer is not present. Biopsy may be indicated in these situations:

- No fluid is aspirated.
- The mammogram shows suspicious findings.
- A mass remains palpable after aspiration.
- The aspirated fluid reveals cancer cells.

Symptoms often resolve after menopause when estrogen decreases.

PATIENT-CENTERED COLLABORATIVE CARE

Management of FBC focuses on the symptoms of the condition. Suggest supportive measures such as the use of mild analgesics or limiting salt intake before menses to help decrease swelling. Wearing a supportive bra can reduce pain by decreasing tension on the ligaments, although some women find that not wearing a bra is more comfortable. Local application of ice or heat may provide temporary relief of pain.

If drug therapy is indicated, oral contraceptives may be prescribed to suppress oversecretion of estrogen, and progestins may be used to correct luteal insufficiency. Danazol (Danocrine, Cyclomen ) suppresses ovarian function and estrogen stimulation of breast tissue. However, because danazol does not cure FBC and because its side effects are undesirable, it is generally used only in patients with recurrent and severe FBC.

! NURSING SAFETY PRIORITY

Drug Alert

Explain to women the benefits and risks associated with drug therapy for FBC, such as stroke, liver disease, and increased intracranial pressure. Teach them to seek medical attention immediately if any signs or symptoms of these complications occur.

Treatment for FBC may also include the use of vitamins C, E, and B complex. Diuretics may be prescribed to decrease premenstrual breast engorgement. Reduction of dietary fat and caffeine has been suggested, although the role of caffeine and fat in FBC is unclear.

Encourage the patient to continue prescribed drug therapy, and monitor the effectiveness of these interventions. Teach

the patient to become familiar with the normal feel and texture of her breasts so she is aware of any changes.

DUCTAL ECTASIA

Ductal ectasia is a benign breast problem that is usually seen in women approaching menopause. It occurs when a breast duct dilates and its walls thicken, causing the duct to become blocked. The ducts in the subareolar area are most often affected. These ducts become distended and filled with cellular debris, which activates an inflammatory response. Two manifestations result from these changes:

- A mass develops that feels hard, has irregular borders, and may be tender.
- A greenish brown nipple discharge, enlarged axillary nodes, and redness and edema over the site of the mass are noted.

Ductal ectasia does not affect a woman's breast cancer risk. However, if a mass is present, it may be difficult to distinguish it from breast cancer. Because the risk for breast cancer is increased among women in the menopause age-group, accurate diagnosis is vital. A microscopic examination of the nipple discharge is performed to detect any atypical or malignant cells, and the affected area is excised. Nursing care is directed at reducing the anxiety associated with the threat of breast cancer and at supporting the woman through the diagnostic and treatment procedures. Ductal ectasia may improve without treatment. Warm compresses and antibiotics may be helpful. If symptoms do not improve, the abnormal duct may be surgically removed.

INTRADUCTAL PAPILLOMA

Intraductal papilloma occurs most often in women 40 to 55 years of age. A benign process in the epithelial lining of the duct forms a **papilloma** (pedunculated outgrowth of tissue). As it grows, trauma and erosion within the duct result in a bloody or serous nipple discharge. A mass is rarely palpable.

Diagnosis is aimed first at ruling out breast cancer. Microscopic examination of the nipple discharge and surgical excision of the mass and ductal area are usually indicated.

ISSUES OF LARGE-BREASTED WOMEN

Although Western society emphasizes large breasts as a positive attribute, women with excessive breast tissue often have health problems and discomfort. For instance, a woman with large breasts may have difficulty finding clothes that fit well and in which she feels attractive. The breast size may be out of proportion to the rest of the body, which adds to the problem of finding clothes that fit. Larger bras are expensive and may need to be specially ordered. The woman may have large dents in the shoulders from bra straps. In addition, many large-breasted women develop fungal infections under the breasts, especially in hot weather, because it is difficult to keep this area dry and exposed to air.

Backaches from the added weight are also common. If well-fitting bras do not help and obesity is not part of the problem, the only alternative for this condition may be breast reduction surgery. The surgeon removes excess breast tissue and then repositions the nipple and remaining skin flaps to

produce the best cosmetic effect. This operation is a major surgical procedure and is called a **reduction mammoplasty**.

The decision to have the procedure is usually made after years of living with the discomfort of excessive breast size. Listen to the woman verbalize her feelings, and reinforce information as appropriate. The nursing care after surgery is similar to that for the woman having reconstructive surgery. (See discussion of Breast Reconstruction, p. 1603, in the Surgical Management section.)

ISSUES OF SMALL-BREASTED WOMEN

Some women choose to have **breast augmentation** surgery to increase or improve the size, shape, or symmetry of their breasts. Most health insurers do not pay for this procedure. Most surgeries involve the implantation of saline-filled or silicon prostheses. Some are constructed from the women's own tissue in much the same way as for reconstruction after mastectomy. *Saline* implants are filled with sterile saline and can be filled with the amount needed to get the shape and firmness the woman wants. If the implant shell leaks, the saline will be safely absorbed by the body. *Silicone* implants are filled with an elastic gel, which can leak into the breast and will not be absorbed. The plastic surgeon reviews the advantages and disadvantages of each implant or natural procedure.

! NURSING SAFETY PRIORITY

Action Alert

Before breast augmentation surgery, teach the patient to stop smoking (to promote healing), avoid aspirin and other NSAIDs, and avoid herbs that can cause bleeding during the procedure, such as garlic, *Ginkgo biloba*, and ginseng. Tell her that the incisions will be hidden as much as possible, either under the pectoral muscle or directly behind the breast tissue as a submammary placement. One or more wound drains will be inserted during surgery, and she will need to know how to care for those drains at home. Review possible postoperative complications, including infection and prosthesis leakage, which can cause severe pain and possible fever.

After surgery, the patient can be discharged to home the same day or the day after. Remind the family or significant other that someone should stay with her for at least 24 hours after surgery. The incisions may or may not have dressings depending on the surgeon and type of surgery.

! NURSING SAFETY PRIORITY

Action Alert

Remind the patient after breast augmentation that for the first few days she should expect soreness in her chest and arms. Her breasts will feel tight and sensitive, and the skin over her breasts may feel warm or may itch. Teach the patient that she will have difficulty raising her arms over her head and should not lift, push, or pull anything until the surgeon permits. Teach her to also avoid strenuous activity or twisting above her waist. Remind the patient to walk every few hours to prevent deep vein thrombi. Tell her to expect some swelling of the breasts for 3 to 4 weeks after surgery.

An important issue for patients who have breast augmentation surgery is breast cancer surveillance. Breast

FIG. 73-1 Gynecomastia.

self-examination (BSE) and clinical breast examination (CBE) are easily performed after prostheses are placed. The prosthesis is placed behind the woman's normal breast tissue, actually pushing it forward. However, screening mammography may not be as sensitive because the amount of visualized breast tissue is decreased. Even though breast cancer detection may be impaired, survival rates for augmented women with breast cancer are not affected (Xie et al., 2010). Likewise, there is no association between breast implants and increased risk for breast cancer (American Cancer Society [ACS], 2010a). Teach women desiring cosmetic breast augmentation about the differences in breast cancer screening.

GYNECOMASTIA

Gynecomastia literally means “female breasts” and is a symptom rather than a disease. It is usually a benign condition of breast enlargement in *men* (Fig. 73-1). However, gynecomastia can be a result of a primary cancer such as lung or testicular cancer. The enlargement is usually bilateral but may be asymmetric in a few cases. The condition is caused by abnormal growth of the glandular tissue, including the mammary ducts and ductal tissue. In many instances, it is difficult to determine gynecomastia from breast enlargement related to excess adipose tissue. Other causes of gynecomastia include:

- Drugs, such as anti-androgen agents and corticosteroids
- Aging
- Obesity
- Underlying disease causing estrogen excess, such as malnutrition, liver disease, or hyperthyroidism
- Androgen-deficiency states, such as age, chronic kidney disease, or alcoholism

Although gynecomastia is not common, men with abnormal breast findings, especially a breast mass, should be carefully evaluated for breast cancer.

BREAST CANCER

Pathophysiology

Excluding skin cancers, breast cancer is the most commonly diagnosed cancer in women and is second only to lung cancer as a cause of female cancer deaths (ACS, 2010a). Therefore most references in this section are to women with breast cancer. Because of the high incidence of the disease, almost every woman knows of someone with the disease. Thus most women have strong reactions to the threat of breast cancer. These reactions greatly influence health habits, including breast self-examination (BSE) and the patient's readiness to seek care when a suspicious area is discovered. Nurses play a key role in early detection by educating women about screening guidelines, risk factors for breast cancer, and BSE. Men should also be taught about this disease.

Early detection is the key to effective treatment and survival. The 5-year relative survival rate is lower for women who are diagnosed with an advanced stage of breast cancer. The 5-year survival rate for localized breast cancer is 98%, whereas the rate drops to 84% when the cancer has spread to the regional lymph nodes (ACS, 2010a). Survival drops dramatically when it is metastatic (spread to distant sites).

Cancer of the breast begins as a single transformed cell that grows and multiplies in the epithelial cells lining one or more of the mammary ducts or lobules. It is a heterogeneous disease, having many forms with different clinical presentations and responses to therapy (Weigelt et al., 2010). Some breast cancers will present as a palpable lump in the breast, whereas others will show up only on a mammogram.

There are two broad categories of breast cancer: noninvasive and invasive. About 20% are *noninvasive*; the remaining 80% are *invasive*. As long as the cancer remains within the duct, it is noninvasive. The cancer is classified as *invasive* when it penetrates the tissue surrounding the duct. Most of these cancers arise from the intermediate ducts. Metastasis occurs when cancer cells leave the breast via the blood and lymph systems, which permits spread of these cells to distant sites. The most common sites of metastatic disease from breast cancer are bone, lungs, brain, and liver. The course of metastatic breast cancer is related to the site affected and to the function impaired. The processes involved in cancer development are described in Chapter 24.

Noninvasive Breast Cancers

Ductal carcinoma in situ (DCIS) is an early *noninvasive* form of breast cancer. In DCIS, cancer cells are located within the duct and have not invaded the surrounding fatty breast tissue. Because of mammography screening and earlier detection, the number of women diagnosed with DCIS has increased. If left untreated, it may spread into the breast tissue surrounding the ducts over a period of years (*invasive breast cancer*). Currently there is no way to determine which DCIS lesions will progress to invasive cancer and which ones will remain unchanged, but research is continuing in this area (Muggerud et al., 2010). *It is important to remember that although DCIS should be treated to prevent it from developing into an invasive breast cancer, it does not metastasize at this stage.*

Another type of noninvasive cancer is **lobular carcinoma in situ (LCIS)**. This cancer type is rare and usually identified incidentally during biopsy for another problem. Having LCIS

FIG. 73-2 Skin dimpling on a breast as a result of fibrosis or breast cancer.

FIG. 73-3 Breast edema giving the skin an “orange peel” (peau d’orange) appearance.

increases one’s risk for developing a separate breast cancer later. Traditionally, LCIS has been treated with close observation only. However, emerging evidence suggests that many LCIS lesions will progress to invasive cancer and should be treated with surgical excision (Cangiarella et al., 2008).

Invasive Breast Cancers

The most common type of invasive breast cancer is **infiltrating ductal carcinoma**. As the name implies, the disease originates in the mammary ducts and grows in the epithelial cells lining these ducts. Once invasive, the cancer grows into the tissue around it in an irregular pattern. If a lump is present, it is felt as an irregular, poorly defined mass. As the tumor continues to grow, **fibrosis** (replacement of normal cells with connective tissue and collagen) develops around the cancer. This fibrosis may cause shortening of Cooper’s ligaments and the resulting typical skin dimpling that is seen with more advanced disease (Fig. 73-2). Another sign, sometimes indicating late-stage breast cancer, is an edematous thickening and pitting of breast skin called *peau d’orange* (orange peel skin) (Fig. 73-3).

A rare but highly aggressive form of invasive breast cancer is **inflammatory breast cancer** (IBC). Symptoms include swelling, skin redness, and pain in the breasts. IBC seldom presents as a palpable lump and may not show up on a mammogram. Because it is usually diagnosed at a later stage than other types of breast cancer, it is often harder to treat successfully (ACS, 2010b).

Breast Cancer in Men

Male breast cancer is rare, occurring in fewer than 1% of all cases. The average age of onset is 60 years. Most cases occur in those with a genetic mutation in either the *BRCA1* or the *BRCA2* gene. (See discussion of genetic risk below.)

Men usually present with a hard, painless, subareolar mass; gynecomastia may be present. Occasionally the man may have nipple discharge, retraction, erosion, or ulceration. Because *men* usually do not suspect breast cancer when they feel a lump, diagnosis frequently is delayed (Mattarella, 2010). The disease is often advanced when diagnosed; thus men have poorer survival than women (ACS, 2010a). Treatment of breast cancer in men is the same as in women at a similar stage of disease.

Breast Cancer in Young Women

Approximately 5% of breast cancer cases occur in women younger than 40 years (ACS, 2010a). Genetic predisposition is a stronger risk factor for younger women than older women (Pollán, 2010). Younger women frequently present with more aggressive forms of the disease. Screening tools are often less effective for this group because the breasts are denser. Women of childbearing age with breast cancer may be concerned about infertility after treatment. Distress about interrupted childbearing can have a major impact on their quality of life (Camp-Sorrell, 2009). Nurses should discuss issues of fertility with patients before chemotherapy. Younger women who experience abrupt menopause as a result of chemotherapy or ovarian suppression also report a greater effect on their sexuality than do older counterparts (McLachlan, 2009).

Etiology and Genetic Risk

There is no single known cause for breast cancer. *Being an older woman or man is the primary risk factor, although some people are at higher risk than others.* Several breast cancer risk factors have been identified; some are modifiable, whereas others are not (ACS, 2010a). Table 73-2 lists major risk factors for breast cancer development.

Although most breast cancers occur in women with no family history of the disease, having a first-degree relative (mother, sister, or daughter) with breast cancer increases the risk for the disease. Having more than one first-degree relative or a relative diagnosed at a younger age further increases one’s risk (ACS, 2010a). Certain genetic factors can increase a woman’s risk for both ovarian and breast cancer. Encourage women with a family history of breast or ovarian cancer to discuss this history with their physician.

Breast cancer is usually a *sporadic* (not having a definite genetic pattern) rather than an inherited or a familial disorder. Many personal and environmental interactions are

GENETIC/GENOMIC CONSIDERATIONS

Mutations in several genes, such as *BRCA1* and *BRCA2*, are related to hereditary breast cancer. People who have specific mutations in either one of these genes are at a high risk for developing breast cancer as well as ovarian cancer. However, only 5% to 10% of all breast cancers are hereditary. Only women with a strong family history and a reasonable suspicion that a mutation is present have genetic testing for *BRCA* mutations (ACS, 2010a). Encourage women to talk with a genetics counselor to carefully consider the benefits and potential harmful consequences of genetic testing before these tests are done.

TABLE 73-2 RISK FACTORS FOR BREAST CANCER

FACTORS	COMMENTS
High Increased Risk (Relative Risk >4.0)	
Female gender	Ninety-nine percent of all breast cancers occur in women.
Age >50 yr	Greatest risk for women is ages 50 to 69 years.
Genetic factors	Inherited mutations of <i>BRCA1</i> and/or <i>BRCA2</i> increase risk.
Family history	Two or more first-degree relatives with breast cancer at an early age increases risk.
History of a previous breast cancer	The risk for developing a cancer in the opposite breast is 5 times greater than for the average population at risk.
Breast density	Dense breasts contain more glandular and connective tissue, which increases the risk for developing breast cancer.
Moderate Increased Risk (Relative Risk 2.1-4.0)	
Family history	One first-degree relative with breast cancer moderately increases risk.
Biopsy-confirmed atypical hyperplasia	The overactive growth of cells increases risk.
Ionizing radiation	Women who received frequent low-level radiation exposure to the thorax had an increased risk, especially if the exposure occurred during periods of rapid breast formation.
High postmenopausal bone density	High estrogen levels over time both strengthen bone and increase breast cancer risk.
Low Increased Risk (Relative Risk 1.1-2.0)	
Reproductive history Nulliparity OR First child born after age 30	Childless women have an increased risk, as do women who bear their first child near or after age 30.
Menstrual history (Early menstruation or late menopause, or both)	The risk for breast cancer rises as the interval between menarche and menopause increases. Women who undergo bilateral oophorectomy before age 35 have less risk for breast cancer than women who undergo natural menopause.
Oral contraceptives	There is a slight increase in breast cancer risk in women taking oral contraceptives.
Hormone replacement therapy (HRT)	Use of estrogen and progestin increases risk; routine use of hormone therapy for osteoporosis and heart disease is no longer recommended.
Obesity	Postmenopausal obesity (especially increased abdominal fat), increased body mass, insulin resistance, and hyperglycemia have been reported to be associated with an increased risk for breast cancer.
Other Risk Factors	
Alcohol	Risk is dose-dependent; consumption of 3 to 14 drinks per week is associated with a slight increase in risk; risk increases with increased consumption.
High socioeconomic status	Breast cancer incidence is greater in women of higher education and socioeconomic background. This relationship is possibly related to lifestyle differences, such as age at first birth.
Jewish heritage	Women of Ashkenazi Jewish heritage have higher incidences of <i>BRCA1</i> and <i>BRCA2</i> genetic mutations.

Modified from American Cancer Society. (2010). *Breast cancer facts & figures 2009-2010*. Atlanta: Author.

related to its development. Known factors that increase risk include exposure to high-dose ionizing radiation to the thorax (especially before 20 years of age), early menarche (before 12 years of age), and late menopause (after 50 years of age). A history of previous breast cancer, nulliparity (no pregnancies), and first birth after 30 years of age also appear to increase risk.

Other causative risk factors not as well explained are nutrition and hormone replacement therapy (HRT). Alcohol is clearly linked to an increased risk for invasive breast cancer. Having an average of one or more alcoholic drinks a day increases the risk up to one and a half times (ACS, 2010a). Obesity also increases breast cancer risk, especially for women after menopause. Fat tissue becomes the major source of estrogen after the ovaries stop functioning. Having a greater amount of fat tissue increases hormonal influence on breast cancer development (ACS, 2010b). An increase in the risk for breast cancer has been shown in postmenopausal women receiving HRT after 5 or more years of use, with the combination of estrogen and progestin carrying the highest

increased risk. However, the use HRT is not considered a major risk factor for breast cancer compared with other breast cancer risks (Bluming & Tavis, 2009). Encourage women seeking help for menopausal symptoms to discuss the benefits and risks of hormonal therapy with their health care provider.

Incidence/Prevalence

In 2010, the projected breast cancer incidence was more than 207,000 women in the United States. Of these, almost 40,000 women are likely to die of the disease (Jemal et al., 2010).

Health Promotion and Maintenance

The American Cancer Society (ACS) establishes evidence-based guidelines for breast cancer screening in women. Guidelines have not been recommended for screening men in the general population because breast cancer in men is so uncommon (ACS, 2010b). Encourage men with a strong family history or known genetic mutations to discuss screening with their health care provider.

CULTURAL AWARENESS

One of every 8 U.S. women will develop breast cancer by age 70. Euro-American women older than 40 years are at a greater risk than other racial/ethnic groups, but African-American women *younger than 40 years* have breast cancer more often than others in that age-group. African-American women have a higher death rate at any age when compared with other women with the disease (ACS, 2010a). This difference has been attributed to limited access to and lower utilization of services for early detection and treatment (ACS, 2010c). Research has also found differences in tumor characteristics in some African-American women (Cunningham et al., 2010). For example, *triple negative breast cancer* occurs more often in African-American women and younger women. In this type of breast cancer, cells lack receptors for estrogen, progesterone, and the protein *HER2*. Triple negative breast cancer tends to be more aggressive than other types of breast cancer, and fewer effective treatments exist for it. Much research is ongoing to better understand this type of breast cancer.

For American Indian and Alaska Native women, 5-year survival rates for breast cancer are very poor (English et al., 2008). These women are less likely than non-Hispanic white women to have mammography screening (Wingo et al., 2008). Health promotion interventions to improve mammography rates should consider cultural customs, transportation, and social support.

Latino and Hispanic women have a lower incidence of breast cancer than Euro-American women but a higher death rate (ACS, 2010d).

Risk factors for Hispanic women are not as well understood as those for non-Hispanic whites, and more research is needed in this area (Hines et al., 2010). Whereas Asian women have better 5-year survival rates than Euro-American women, the rates for Native Hawaiian women are slightly poorer than Euro-American women (ACS, 2010a). Strategies that have increased breast cancer screening in the Native Hawaiian population include the use of lay educators and community cancer outreach programs (Aitaoto et al., 2009).

recommended against routine screening mammography in average-risk women ages 40 to 49 years and older than 75 years, concluding there is only a small net benefit for women in these age-groups (USPSTF, 2009). Scientific evidence shows there are benefits as well as risks associated with mammography, and disagreement exists about the emphasis that should be placed on each one. However, the ACS and The American College of Obstetricians and Gynecologists (ACOG) continue to recommend that all women age 40 and older have a screening mammogram annually (ACOG, 2011). Nurses working with women must be able to educate women on the risks and benefits of breast screening techniques so that they can make informed decisions about the screening methods best suited to their individual situations (Association of Women's Health, Obstetric, and Neonatal Nursing [AWHONN], 2010).

Women with known genetic mutations or other high risk factors for breast cancer should have screening with magnetic resonance imaging (MRI) in addition to annual mammography (ACS, 2010b). Encourage women with moderate risk factors to discuss with their health care provider the benefits and limitations of adding MRI screening to their annual mammograms. MRI screening is not recommended for women with low breast cancer risk factors.

Breast Self-Awareness/Self-Examination

Nurses working with women should teach them the importance of becoming familiar with the appearance and feel of their breasts. Any changes detected by the woman should be reported to her health care provider. Teach a woman that lumps are not necessarily abnormal. For premenopausal women, lumps can come and go with the menstrual cycle. Most lumps that are detected and tested are not cancerous.

Some women may want to practice regular breast self-examination (BSE) as a method for breast self-awareness. Evidence shows that monthly BSE is no more beneficial than women simply being aware of what is normal for their own breasts and women are just as likely to find a lump by chance (ACS, 2010b). However, BSE should be presented as an option to women beginning in their early 20s. In addition to breast self-awareness, emphasis should be placed on mammography and clinical breast examination for early detection of breast cancer. The combined approach is better than any single test (ACS, 2010a). A woman who chooses to perform BSE should be taught the correct technique and have it reviewed by a health care professional during her clinical breast examination.

Teach patients how to perform BSE if they choose. The examination technique is similar for women and men. Use teaching models of normal and abnormal breasts when teaching BSE. Discuss the proper timing for BSE. Instruct premenopausal women to examine their breasts 1 week after the menstrual period. At this time, hormonal influence on breast tissue is decreased, so fluid retention and tenderness are reduced. Teach women whose breast tissue is no longer influenced by hormonal fluctuations, such as after a total hysterectomy or menopause, to pick a day each month to do BSE, such as the first day of the month.

Ensure that the setting in which you demonstrate BSE is private and comfortable. Ask the woman to undress from the waist up, and provide a gown and sheet. Teach the woman to stand in front of a mirror to inspect the breast for abnormalities. She should raise her arms above her head and press her hands on her hips to emphasize any changes in the shape of

NCLEX EXAMINATION CHALLENGE

Health Promotion and Maintenance

When teaching women about the risk for breast cancer, which risk factor does the nurse know is the most common for the development of the disease?

- A. Having an aunt with breast cancer
- B. Being an older adult
- C. Being a Euro-American
- D. Consuming a low-fat diet

The ACS recommendation for early detection by screening for breast masses is a screening mammogram for women ages 40 years and older and a clinical breast examination (CBE) by a health professional at least every 3 years for women 20 to 40 years old. Monthly breast self-examination (BSE) is less emphasized today than in the past several decades.

NURSING SAFETY PRIORITY

Action Alert

Teach women that no single method for early detection of breast cancer is effective when used alone. The best approach for average-risk women is screening mammogram, clinical breast examination, and breast self-awareness.

Mammography

The use of mammography (x-ray of the breasts) screening for healthy, average-risk women has been a subject of recent controversy among various scientific and advocacy groups. In 2009, the U.S. Preventive Services Task Force (USPSTF)

the breasts. Palpation should be performed in a lying position and while bathing or showering. Before teaching breast palpation, ask the woman to demonstrate her own method. If she is unsure or has not performed BSE before, slowly lead her through the examination while explaining the rationale for the technique and answering questions. Demonstrate the correct technique of examining the breasts with the arm overhead instead of having the arm by her side. Showing the difference in the two positions, especially in large-breasted women, reveals the advantage of using the correct method, which spreads the tissue over the chest wall for more effective palpation (Fig. 73-4).

It is also helpful to point out different findings at this time, especially those that the woman might perceive as abnormal. Placing the woman's hand directly on the involved area and showing her precisely what is normal for her can build self-confidence. Teach her that nodular breast tissue may normally feel lumpy, which may be interpreted as widespread cancer. Indicate the *inframammary ridge*, the area of the breast where the skin folds under the breast. This thickened area may be perceived as a lump instead of a normal finding. In thin or small-breasted women, the ribs may be mistaken for masses. Demonstrate how to follow the rib to the sternum to be sure that what she is feeling is bone and not breast tissue.

Any one of three palpation methods can be used to examine the breast tissue (Fig. 73-5). Teach the importance of covering all tissue during palpation. Demonstrate the proper amount of pressure needed to palpate the breast tissue and the correct position of the hands. The finger pads, which are more sensitive than the fingertips, are used when palpating the breasts. Teach the woman to press firmly enough to detect the underlying tissue.

Clinical Breast Examination

Clinical breast examination (CBE) is typically performed by advanced practice nurses and other health care providers. However, nurses in general practice who are skilled in the technique can also perform the procedure. It is recommended that the CBE be part of a periodic health assessment, at least every 3 years for women in their 20s and 30s and every year for asymptomatic women at least 40 years of age (ACS, 2010a). Provide a private and comfortable setting, protect the patient's dignity, and allow time for discussion.

FIG. 73-6 A breast evaluation form.

Taking a breast history is vital. Results may be recorded on a breast evaluation form, which is a part of the medical record (Fig. 73-6). This record helps establish the woman's risk for breast disease and the need for follow-up diagnostic tests, such as mammograms, and teaching.

The physical assessment begins with inspection. The woman undresses from the waist up and first sits or stands with her hands by her sides. The examiner inspects the breasts for symmetry and size, contour, skin changes (color, texture, and venous patterns), nipple changes, and lesions.

One breast may be larger than the other, and inverted nipples are common. Ask the woman whether these findings are normal for her. Any change in symmetry may indicate a problem. The contour should be even, and the skin should have a smooth texture. Venous patterns may be visible but should be similar bilaterally. The nipples and areolae should be equal or nearly equal in size and should be a similar color. The nipples may be wrinkled or smooth, and Montgomery's tubercles on the areolae are normal. Extra nipples, although rare, are also normal and may appear anywhere on the chest. If present, they should be examined in the same manner as the normal nipples.

While the arms are by the side and relaxed, palpate the axillae (underarms) and the area above and below the clavicle

for enlarged lymph nodes. If it is necessary to move the arms away from the body, the woman should rest her arm on the examiner's to prevent flexion of the underlying muscles. The woman is then asked to raise her arms over her head, which exposes the sides and underneath portions of the breast for inspection. Finally, she is asked to place her hands on her hips and press, thus flexing the pectoral muscles. This action shows skin dimpling, retractions, or masses.

The remainder of the examination is done with the patient lying supine. Place a pillow or rolled sheet under the patient's shoulder, and the arm on that side is raised above the head. Each breast is palpated separately while the other breast remains covered. If the patient has identified a problem in one breast, the "normal" breast is examined first to establish a baseline for comparison.

For a clinical breast examination, the vertical strip, three-pressured method is the most effective technique for detecting breast cancer at its earliest stages. Every inch of the breast tissue should be palpated using light, medium, and then deep pressure. If a mass is palpated, note its position by viewing the breast as a clock face (with the 12 o'clock position being toward the woman's head) and noting the "area of the clock" where the mass is located. Palpate the tail of Spence, which extends from the upper outer quadrant of the breast into the

axilla. The supraclavicular lymph nodes are palpated for the presence of any enlarged nodes by hooking the fingers over the clavicle.

Finally, the nipple is gently compressed to detect the presence of a discharge. If a discharge is produced, note the “area of the clock” where the breast was compressed when the discharge was released. If there is a history of discharge, the woman may be able to express the discharge more successfully than the examiner can and should be asked to do so.

Discovery of a suspicious lesion or discharge during the examination requires referral to a health care provider who specializes in caring for breast disorders. Follow-up usually involves mammography and possibly ultrasound. If there is a dominant mass or high genetic risk, the woman should be referred for biopsy even if the mammogram is negative.

CONSIDERATIONS FOR OLDER ADULTS

As women age, the breast tissue becomes flattened and elongated and is suspended loosely from the chest wall. On palpation, the breast tissue of the older woman has a finer, more granular feel than the lobular feel in a younger woman. The inframammary ridge may be more prominent as a result of atrophy of the breast tissue. Breast examination in older adults may be easier because of tissue atrophy and relaxation of the suspensory ligaments.

Women in nursing homes and other chronic care facilities often do not have clinical breast examinations and may not be deliberately aware of the normal appearance and feel of their breasts. Teach the importance of breast self-awareness and reporting any breast changes the woman may notice. Teach BSE as an option for older women who are comfortable with and able to perform this method. Collaborate with the health care provider to ensure that residents have clinical breast examinations.

Options for High-Risk Women

Women with a personal history of breast cancer are at risk for developing a recurrence or a new breast cancer. Those with known *BRCA1* and *BRCA2* genetic mutations, strong family history, or other high risk factors are also considered high-risk. Women in this category usually practice *close surveillance* as a prevention option. It is referred to as “secondary prevention” and is used to detect cancer early in the initial stages. In addition to annual mammography and clinical breast examination, high-risk women are recommended to have an annual breast MRI screening (ACS, 2010a). Close surveillance may begin as early as age 30, but evidence is limited regarding the best age at which to start screening. Encourage high-risk women to discuss their personal preferences for close surveillance with their health care providers.

Options currently available for reducing a woman's breast cancer risk are **prophylactic mastectomy** (preventive surgical removal of one or both breasts), prophylactic **oophorectomy** (removal of the ovaries), and anti-estrogen chemopreventive drugs. Although each option significantly reduces the risk for breast cancer, no option completely eliminates it. Each option has its own risks and potentially serious complications.

Even though a woman may decide to have a prophylactic mastectomy, there is a small risk that breast cancer will develop in residual breast glandular tissue because no mastectomy reliably removes all mammary tissue. Women must also understand that breast reconstruction after a prophylactic mastectomy is very different from breast augmentation. It

is a more complex surgical procedure with a greater potential for complications.

Women undergoing oophorectomy will likely experience menopausal symptoms, and they will still have some estrogen stored in body fat tissue. Antiestrogen drugs reduce breast cancer recurrence but carry other risks such as blood clots and endometrial cancer. Encourage women to carefully consider the benefits and risks of breast cancer–risk-reducing options and discuss them with their health care provider.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

History

Often the history is taken after a mass has been discovered but before a diagnosis has been made for a woman or man with breast cancer. For some patients, the history may be obtained at the time they are seen for treatment of an identified cancer. The interview should focus on three major areas: risk factors, the breast mass, and health maintenance practices.

Record age, gender, marital status, weight, and height. Marital status and identifying the patient's primary support person provide information about who should be included in the patient's care, teaching, and support.

CULTURAL AWARENESS

Remember that some cultures do not allow the man to be part of a woman's care or only women are allowed to care for her (e.g., Arab Muslim women). Other cultures are male-predominant, and all decisions about female care are made by the man (e.g., Nigerian women).

Chapter 4 describes additional general cultural considerations related to health care.

Ask specific information on personal and family histories of breast cancer. In addition to increasing the woman's own risk, these factors also affect any sisters' or daughters' risk and should be part of later counseling.

Ask about the woman's gynecologic and obstetric history, including:

- Age at menarche
- Age at menopause
- Symptoms of menopause
- Age at first child's birth
- Number of children/pregnancies

Prolonged hormonal stimulation (e.g., early menses, late menopause) increases a woman's risk, as do birth of the first child after 30 years of age and nulliparity (having no children).

A history of the breast mass or lump reveals not only the course of the disease but also information related to health care-seeking practices and health-promoting behaviors. Ask the patient about how, when, and by whom the mass was discovered and the time between discovery and seeking care. If the patient found the mass, ask how it was discovered. The answer to this question reveals the need for discussion and teaching about health promotion practices, regardless of whether the mass proves to be cancerous. If there was a delay between discovery and seeing the health care provider, ask

CHART 73-1 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Assessing a Breast Mass

- Identify the location of the mass by using the “face of the clock” method.
- Describe the shape, size, and consistency of the mass.
- Assess whether the mass is fixed or movable.
- Note any skin changes around the mass, such as dimpling (*peau d’orange*), increased vascularity, nipple retraction, and ulceration.
- Assess the adjacent lymph nodes, both axillary and supraclavicular nodes.
- Ask patients if they experience pain or soreness in the area around the mass.

what caused the delay. These questions are linked to the psychosocial assessment but also reveal the length of time that the tumor has been present. Ask what procedures have been performed to diagnose the problem. Also, ask patients if they have noticed any other changes in their body within the past year. This information can help determine whether there has been obvious cancer spread. Ask especially about the presence of joint or bone pain.

Ask about the use of alcohol intake, because this is a factor that may increase breast cancer risk. Ask what prescribed and over-the-counter (OTC) drugs are used, specifically, hormonal supplements such as estrogen and natural or herbal substances that stimulate hormones. Estrogen can be taken orally, intravaginally, or via a transdermal patch. Document the type and form of hormones (birth control pills or patches, supplements) and length of use.

Physical Assessment/Clinical Manifestations

Document in the medical record any abnormal findings from the clinical breast examination. Describe specific information about a breast mass (Chart 73-1) such as location, using the “face of the clock” method; shape; size; consistency; and whether the mass is mobile or fixed to the surrounding tissue. Note any skin change, such as *peau d’orange* (dimpling, orange peel appearance), redness and warmth, nipple retraction, or ulceration, which can indicate advanced disease. Document the location of any enlargements of axillary and supraclavicular lymph nodes. Evaluate the presence of pain or soreness in the affected breast.

Psychosocial Assessment

A breast cancer diagnosis is usually an unanticipated event in the life of a woman who feels physically well. It initiates a sudden and distressing transition into a potentially life-threatening illness. Feelings of fear, shock, and disbelief are predominant as a woman learns about her disease and faces numerous treatment decisions. As a result, the period between diagnosis and treatment is one of the most demanding and stressful times for women with breast cancer (Lally, 2010). Use psychosocial interventions and appropriate therapeutic communication skills to assist women to cope effectively during this time.

Assess the patient’s need for information. Some people may not be ready for a lot of information at first. Most want to know how advanced the disease is, the likelihood of cure, treatment options and side effects, how treatment will affect

their life and self-image, how family or partners will be affected, and what is required for home self-management. A previous experience with cancer, especially with other people who had breast cancer, influences the reactions to the disease. Ask patients and family members whether they have known anyone with breast cancer, and explore their feelings about the disease. Provide current information about the stage of the disease and treatment options. Determine if a referral to a breast cancer support group would be helpful. Talking with someone who has been through the experience is particularly helpful in dealing with the emotional aspects of the disease.

Also assess the patient for problems related to *sexuality*. Sexual dysfunction affects up to 90% of women treated for breast cancer, although it is an issue seldom discussed between patients and health care providers (Dizon, 2009). Lack of libido (sexual desire) related to hormonal changes, psychological distress, and severe anxiety are commonly experienced by women with breast cancer. If the patient does not discuss sexual concerns voluntarily, ask about the frequency of and satisfaction with sexual relations with her partner. Use resources that provide education about alternative expressions of intimacy and a focus on pleasure rather than performance. Refer the patient and her partner to counseling if appropriate.

Laboratory Assessment

The diagnosis of breast cancer relies on pathologic examination of tissue from the breast mass. After the diagnosis of cancer is established, laboratory tests, including pathologic study of the lymph nodes, help detect possible metastases. Elevated liver enzyme levels indicate possible liver metastases, and increased serum calcium and alkaline phosphatase levels suggest bone metastases.

Imaging Assessment

Mammography is a sensitive screening tool for breast cancer. The uniqueness of this test results from its ability to reveal preclinical lesions (masses too small to be palpated manually). Traditional film mammography is increasingly being replaced by *digital mammography* in most Western countries (Skaane, 2009). *Digital mammography* has the advantage of being able to read, file, and transmit mammograms electronically. Studies have shown a slightly greater benefit from digital mammography in women who have dense breasts, such as those younger than 50 years. Patient preparation and the procedure for mammography are discussed in Chapter 72.

Ultrasonography of the breast is an additional diagnostic tool used to clarify findings on mammography. If the mammogram reveals a lesion, ultrasonography is helpful in differentiating a fluid-filled cyst from a solid mass. Mammography screening combined with ultrasound is also more effective for detecting cancers in women with dense breasts (Nothacker et al., 2009).

Magnetic resonance imaging (MRI) may be used to better examine suspicious areas found by a mammogram or for women with dense breasts. It can help determine the actual size of the cancer and look for any other cancers in the breast (ACS, 2010b). Some facilities may offer other types of imaging tests such as *breast-specific gamma imaging (BSGI)* and *positron emission mammography (PEM)*. These tests require the patient to be injected with a small amount of tracing agent that concentrates in the tumor area if present. The agent

emits x-rays that the imaging system can detect. In some cases, these tests detect cancers not seen with traditional imaging.

If the patient has an invasive breast cancer, other imaging tests may be done to rule out metastases. A chest x-ray is done to screen for lung metastases. Bone, liver, and brain scans and computed tomography (CT) scans of the chest and abdomen can reveal distant metastases.

Other Diagnostic Assessment

Whereas imaging techniques serve as tools for screening and more precise visualization of potential breast cancers, *breast biopsy (pathologic examination of the breast tissue) is the only definitive way to diagnose breast cancer*. Breast tissue is obtained by one of several types of biopsies (see Chapter 72). Tissue samples are analyzed by a pathologist to determine the presence of breast cancer. If breast cancer is identified, it is classified according to the size and type of breast cancer, the histologic grade, and the type of receptors on the cells. These characteristics are used to guide treatment. For example, a small, noninvasive breast cancer may be treated only with lumpectomy and radiation, whereas a larger, aggressive tumor (one with a high histologic grade) may be treated with a mastectomy and chemotherapy, followed by radiation. Cancer cells that contain estrogen receptors (*ER positive*) or progesterone receptors (*PR positive*) have a better prognosis and usually respond to hormonal therapy. If the type of breast cancer is *HER2*, or one in which the *neu* gene product is overexpressed, it may be treated successfully with trastuzumab (Herceptin), which is a breast cancer *targeted therapy* for this specific type.

Most women, even those with very small tumors, receive some sort of treatment in addition to surgery for breast cancer. Research has focused on ways to predict clinical outcomes so that low-risk women may avoid unnecessary treatments. Gene expression profiling systems, such as Oncotype DX and MammaPrint, have been developed to help predict clinical outcomes by analyzing genes in breast cancer tissue. Some clinicians use this information in addition to the pathologic analysis for guiding treatment decisions. However, appropriate treatment recommendations are often made without using these tests (Sotiriou & Pusztai, 2009). More research is underway to develop new systems for predicting outcomes that focus on molecular subgroups in breast cancer.

ANALYSIS

The priority problems for breast cancer include:

1. Ineffective Coping related to unanticipated breast cancer diagnosis
2. Potential for metastasis of cancer to other parts of the body

PLANNING AND IMPLEMENTATION

Developing Coping Strategies

Planning: Expected Outcomes. The patient with breast cancer is expected to report the use of methods to help increase coping ability and reduce anxiety. The patient will maintain relationships and participate as an active partner in management of her disease.

Interventions. The anxiety and uncertainty for the patient with breast cancer begin the moment a lump is discovered or when a mammogram reveals an abnormality. These feelings

may be related to past experiences and personal associations with the disease. Assess the patient's perceptions of his or her own situation. Allow the patient to ventilate these feelings even if a diagnosis has not been established.

If the mass has been diagnosed as cancer, many people feel a partial sense of relief to be dealing with a known entity. A feeling of shock or disbelief usually occurs. It is difficult to accept a diagnosis of cancer when one feels basically well. Patients and their families or significant others deal in individual ways with the mix of feelings. Flexibility is the key to nursing care. Adjust your approach to care as the patient's emotional state changes. Those who have an interval between the diagnosis and treatment, during which they actively participate in the choice of treatment, cope more effectively after surgery, no matter which treatment is chosen.

An integral part of the plan to meet these emotional needs is the use of outside resources. Health care providers working with breast cancer may know other patients willing to make a preoperative visit. For example, the patient who is worried in particular about the side effects of radiation therapy may benefit more from talking to someone who has undergone radiation than from talking to the nurse or health care provider. Be sure to assess his or her preference.

Assess the patient's need for knowledge. Some may want to read and discuss any available information. Provide accurate information, and clarify any misinformation the patient may have received by the media, on the Internet, or from family and friends. The American Cancer Society (www.cancer.org) and Breastcancer.org (www.breastcancer.org) are two Internet sources that provide evidence-based information in language a lay person can understand.

! NURSING SAFETY PRIORITY

Action Alert

Women are exposed to many misconceptions and much misinformation about breast cancer through various media. Clarify misconceptions and provide current information regarding risk factors, screening recommendations, and treatment for breast cancer.

Decreasing the Risk for Metastasis

Planning: Expected Outcomes. The patient with breast cancer is expected to remain free of metastases or recurrence of disease, if possible. If cancer recurs, the patient will experience optimal health outcomes, including potential palliation and end-of-life care.

Interventions. There are many surgical and nonsurgical options for breast cancer treatment. Because of the various options, the patient with breast cancer often faces difficult decisions. Although patients are living longer with metastatic disease, the 5-year survival rate remains low. Newer therapeutic regimens are needed to improve outcomes for these patients (Liu et al., 2010). Once cancer is diagnosed, the extent and location of metastases determine the overall therapeutic strategy. The emphasis of breast cancer treatment is on preventing or stopping the spread of tumor cells that leads to distant metastasis. Treatment is tailored specifically to each patient, taking into account other health problems and the patient's ability to tolerate a particular therapy.

Nonsurgical Management. For patients with breast cancer at a stage for which surgery is the main treatment,

follow-up with adjuvant (in addition to surgery) radiation, chemotherapy, hormone therapy, or targeted therapy is commonly prescribed. For those who cannot have surgery or whose cancer is too advanced, these therapies are used to promote comfort (palliation). These options are discussed in the Adjuvant Therapy section on p. 1605.

Complementary and Alternative Therapies. Women with breast cancer often cope with distressing symptoms related to the disease itself or the side effects of chemotherapy, radiation, and hormonal therapy. Common symptoms associated with these therapies include pain, nausea, hot flashes, anxiety, depression, and fatigue. Physical and emotional symptoms associated with breast cancer may be eased with the use of complementary and alternative medicine (CAM). Up to 80% of women use some form of CAM during breast cancer treatment (Wyatt et al., 2010). The most frequently used types of CAM are biologically based therapies such as vitamins, special cancer diets, and herbal therapy. Prayer is also widely used. Other types of CAM are mind-body or body-based such as guided imagery and massage. Encourage women to seek a practitioner with a certification or license for the specific type of CAM therapy. In some states, a certification or license is required for acupuncture, chiropractic therapy, massage, and shiatsu. Some types of CAM can be self-taught or done alone after a few sessions of instruction. Table 73-3 lists complementary therapies for specific symptoms associated with breast cancer and its treatments.

There is no proven benefit to using CAM alone as a cure for breast cancer. Therefore *nurses must ensure that patient choices can be safely integrated with conventional treatment for breast cancer* (Wyatt et al., 2010). Encourage patients who are interested in trying CAM therapies to check with their health care provider before using them. Refer patients to reliable resources for information about CAM. The website *breast-cancer.org* provides accurate information about complementary therapies and the extent to which they have been researched in breast cancer patients. Cost may be a factor in decision making, since not all insurances provide coverage for

CAMs. Teach the patient that all ingested CAM agents potentially risk interaction with conventional drugs.

! NURSING SAFETY PRIORITY

Action Alert

Teach women that some complementary and alternative therapies can have risks and side effects for women with breast cancer. Acupuncture should be avoided in women experiencing lymphedema, bleeding disorders, or a low white blood cell count from chemotherapy. Soy and soy products also may not be safe for women with breast cancer (see Evidence-Based Practice box below).

Surgical Management. The most common types of breast surgeries are shown in Fig. 73-7. Although controversy exists concerning the best treatment for breast cancer, experts agree that the mass itself should be removed to reduce the risk for local recurrence. A large tumor is sometimes treated with chemotherapy, called **neoadjuvant therapy**, to shrink the tumor before it is surgically removed. An advantage of this therapy is that cancers can be removed by lumpectomy rather than mastectomy.

Axillary lymph nodes are analyzed for the presence of cancer and staging purposes. Axillary lymph node dissection (ALND) is usually done when there are palpable axillary lymph nodes or when cancer is suspected to be at a later stage. Sentinel lymph node biopsy (SLNB) is a much less invasive approach now preferred by most surgeons for analyzing lymph nodes in early-stage breast cancers with low to moderate risk for lymph node involvement. In this method, the sentinel lymph node is identified during breast surgery by injecting the breast with radioisotope and/or dye that travels via lymphatic pathways to the sentinel lymph node. The nodes that take up the dye (or give off a certain level of radiation picked up by a handheld counter) are removed and examined for the presence of cancer cells. It is believed that

TABLE 73-3 COMPLEMENTARY AND ALTERNATIVE MEDICINE (CAM) FOR BREAST CANCER

SYMPTOM	CAM
Physical	
Pain	Acupuncture, chiropractic therapy, hypnosis, massage, music, reiki, shiatsu
Nausea/vomiting	Acupuncture, aromatherapy, ginger, hypnosis, progressive muscle relaxation, shiatsu
Fatigue	Acupuncture, massage, meditation, reiki, tai chi, yoga
Hot flashes	Acupuncture, black cohosh, flaxseed
Muscle tension	Aromatherapy, massage, shiatsu
Emotional	
Anxiety/stress/fear	Aromatherapy, guided imagery, hypnosis, journaling, massage, meditation, music therapy, progressive muscle relaxation, prayer, support groups, tai chi, yoga
Depression	Aromatherapy, yoga, journaling, progressive muscle relaxation

EVIDENCE-BASED PRACTICE

Is There a Relationship Between the Intake of Dietary Soy and Breast Cancer Risk?

Enderlin, C., Coleman, E., Stewart, C., & Hakkak, R. (2009). Dietary soy intake and breast cancer risk. *Oncology Nursing Forum*, 36(5), 531-539.

The relationship between dietary soy and breast cancer risk was studied using a meta-synthesis of findings from health research articles published from January 1997 through June 2008. A total of 364 publications were located, and 34 studies met the criteria for the review. The researchers found that naturally-occurring dietary intake of soy food or its components appears safe for women without breast cancer; however, the safety of high supplements of soy or its components is less certain.

Level of Evidence: 1

The authors performed a meta-synthesis of findings from multiple studies to answer the research question.

Commentary: Implications for Research and Practice

Nurses should become more knowledgeable about soy foods and supplements. When assessing dietary intake, ask women about soy and soy food consumption. Women with breast cancer or those at a known or high risk for breast cancer should avoid including high intake of soy dietary supplements until their possible effects are better understood.

if cancer cells have traveled through the lymph channels, the cells will lodge in the sentinel nodes. Travel beyond these nodes to higher-level nodes may occur as a secondary event. Therefore the absence of cancer cells in the sentinel nodes is an indicator that no other nodes in the regional area are involved.

Preoperative Care. Care of the patient facing surgery for breast cancer focuses on psychological preparation and

preoperative teaching. Priority nursing interventions are directed toward relieving anxiety and providing information to increase patient knowledge. *Include the spouse or partner, who may be experiencing similar stress and confusion, in the health teaching, unless the patient's culture does not permit this approach.*

Review the type of procedure planned. Use open-ended questions (e.g., "What type of surgery are you having? Can

NORMAL ANATOMY

FIG. 73-7 Surgical management of breast cancer.

you explain what will happen?”) to assess the current level of knowledge. Provide postoperative information, including:

- The need for a drainage tube
- The location of the incision
- Mobility restrictions
- The length of the hospital stay (if any)
- The possibility of adjuvant therapy
- General preoperative and postoperative information needed by any surgical patient (see [Chapters 16 and 18](#))

Supplement teaching with written or electronic (DVD) materials for the patient and family to take home as references. This information should include who to call in case there are any complications. Address body image issues before surgery to correct misconceptions about appearance after surgery. If available, suggest that patients and their caregivers attend classes before surgery in an ambulatory care setting, such as a breast cancer center, to promote successful early discharge from the hospital. Programs that provide emotional support, information, and opportunities for discussion related to sexuality, body image, and preoperative and postoperative care enhance the recovery of the short-stay mastectomy patient.

Operative Procedures. During **breast-conserving surgery**, such as a *lumpectomy*, the surgeon removes the tumor and a small amount of tissue rather than the entire breast. This procedure is used primarily for stage I and stage II breast cancer. *Margins* refer to the distance between the tumor and the edge of the tissue. The desired outcome of breast-conserving surgery is to obtain *negative margins* in which no cancer cells extend to the edge of the tissue. Typically, radiation therapy follows to kill any residual tumor cells.

Breast-conserving procedures are usually performed in same-day surgical settings. The cosmetic results of these surgeries are good to excellent, and the psychological benefits of avoiding breast removal are significant for patients who choose this option.

The **modified radical mastectomy** does *not* conserve the breast; the affected breast is completely removed. Indications for a modified radical mastectomy include multi-centric disease (tumor is present in different quadrants of the breast), inability to have radiation therapy, presence of a large tumor in a small breast, and patient preference. The breast tissue, skin, and axillary nodes are removed, and the underlying muscles are left in place. The typical incision is a 4- to 5-inch-long elliptic incision from the midchest to the axilla (see [Fig. 73-7](#)). If reconstruction is to follow the procedure, the plastic surgeon may recommend a different location for the incision. When reconstruction is to be performed at the same time as the mastectomy, less-invasive techniques, such as incising a 1½-inch flap of skin around the nipple (excising the same amount of breast tissue as with conventional mastectomy), may be performed. Skin flaps or expanders may be used to create a breast mound at the time of the original procedure.

Postoperative Care. Before the patient returns from surgery, inform the staff to avoid using the affected arm for measuring blood pressure, giving injections, or drawing blood. He or she returns from the postanesthesia care unit (PACU) as soon as vital signs return to baseline levels and if no complications have occurred. Assess vital signs on a schedule of decreasing frequency, such as every 30 minutes for two times, every hour for two times, and then every 4 hours. During these checks, assess the dressing for bleeding.

FIG. 73-8 Jackson-Pratt drain in place after a mastectomy.

During a *modified radical mastectomy*, the surgeon places one or two drainage tubes, usually Jackson-Pratt drains, under the skin flaps and attaches the tubes to a small collection chamber ([Fig. 73-8](#)). Gentle suction is exerted, and fluid that would accumulate under the flaps and delay healing is collected. Various drains are available, but all allow the drainage to be seen and measured. When taking vital signs, monitor for the amount and color of drainage. Add this information to the intake and output record. Patients undergoing a *lumpectomy* may also have drainage tubes (usually Jackson-Pratt drains) placed if the lump is large or if axillary node dissection is performed.

! NURSING SAFETY PRIORITY

Action Alert

After breast surgery, observe the surgical wound for signs of swelling and infection throughout recovery. With short hospital stays, drainage tubes are usually removed about 1 to 3 weeks after hospital discharge when the patient returns for an office visit. The drainage amount should be less than 25 mL in a 24-hour period. Inform the patient that tube removal may be uncomfortable although these tubes lie just under the skin. Provide or suggest analgesia before they are removed.

Assess the patient's position to ensure that the drainage tubes or collection device is not pulled or kinked. The patient should have the head of the bed up at least 30 degrees with the affected arm (the arm on the same side as the axillary dissection) elevated on a pillow while awake. Keeping the affected arm elevated promotes lymphatic fluid return after removal of lymph nodes and channels. Provide other basic comfort measures, such as repositioning and analgesics as prescribed on a regular basis until pain ceases. Patient-controlled analgesia may be used for some patients for a short time depending on the type of surgery that was performed.

CHART 73-2 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Postmastectomy Exercises

Hand Wall Climbing

- Face the wall, and put the palms of your hands flat against the wall at shoulder level.
- Flex your fingers so that your hands slowly “walk” up the wall.
- Stop when your arms are fully extended.
- Slowly “walk” your hands back down the wall until they return to shoulder level.

Pulley Exercise

- Drape a 6-foot-long rope over a shower curtain rod or over the top of a door. If you use a door for this exercise, have someone put a nail or hook at the top of the door so that the rope does not slip off.
- Grab the ends of the rope, one in each hand, and extend your arms out to your sides until they are straight.
- Keeping your arms straight, pull down with your left arm to raise your right arm as high as you can.
- Pull down with your right arm to raise your left arm as high as you can.

Rope Turning

- Tie a rope to the knob of a closed door.
- Hold the other end of the rope and step back from the door until your arm is almost straight out in front of you.
- Swinging the rope in a circle. Start with small circles, and gradually increase to larger circles as you become more flexible.

! NURSING SAFETY PRIORITY

Action Alert

Assess the incision and flap of the post-mastectomy patient for signs of bleeding, infection, and poor tissue perfusion. Document and report abnormal findings to the surgeon immediately!

The hospital stay after breast surgery is short, often same-day or just overnight, and recovery is usually not complicated. Because some managed care plans will not authorize an overnight stay in the hospital after a mastectomy, several states have enacted legislation mandating inpatient benefits. The patient who chooses an early discharge should have a home care visit within 24 hours of the discharge.

Ambulation and a regular diet are resumed by the day after surgery. While the patient is walking, the arm on the affected side may need to be supported at first. Gradually, the arm should be allowed to hang straight by the side. Instruct the patient to avoid the hunched-back position with the arm flexed because of the risk for elbow contracture. Beginning exercises that do not stress the incision can usually be started on the first day after surgery. These exercises include squeezing the affected hand around a soft, round object (a ball or rolled washcloth) and flexion/extension of the elbow. The progression to more strenuous exercises depends on the subsequent procedures planned (e.g., reconstruction) and the surgeon's prescription.

As soon as the patient is ambulatory and surgical pain is under control, he or she is discharged to home. Common instructions for exercises after mastectomy are listed in [Chart 73-2](#).

NCLEX EXAMINATION CHALLENGE

Physiological Integrity

The nurse is assigned to care for a client immediately after breast-conserving surgery for cancer. What is the priority for care of the client at this time?

- Teach the client to sleep in the prone position each night.
- Empty wound drains and record the output amount.
- Remind the client how to perform breast self-examination.
- Monitor the incision and flap for adequate tissue perfusion.

Breast Reconstruction. Breast reconstruction after or during mastectomy for women is common with few complications. Patients consult with the plastic surgeon to discuss the type of reconstruction, timing of the procedure, and technique desired. Many women prefer reconstruction immediately after mastectomy using their own tissue (autogenous reconstruction). Breast reconstruction at the time of mastectomy, both autogenous and prosthetic, may lessen the psychological strain associated with undergoing a mastectomy.

The surgeon should offer the option of breast reconstruction before surgery is performed. If the woman does not choose immediate reconstructive surgery, a temporary prosthesis can be used. Refer the patient to the American Cancer Society's Reach to Recovery program (www.cancer.org). In this program, a volunteer who has had breast cancer surgery visits the woman at home, offering information on breast forms, clothing, coping with breast cancer, and possible reconstructive options. For this intervention to be as helpful as possible, the volunteer should be about the same age as the patient and have experienced the same surgical procedure.

Evaluate the woman's level of satisfaction with her prosthesis several weeks after surgery. Assess her attitude by asking about future plans for restoring appearance. Although reconstruction is not appropriate for some women and others may not be interested in it, the surgeon should discuss the indications and contraindications, advantages and disadvantages, and typical recovery. If immediate reconstruction is chosen, the surgeon should be aware of this before surgery so that plans can be coordinated with those of the plastic surgeon.

Several procedures are available for restoring the appearance of the breast ([Table 73-4](#)). Reconstruction may begin during the original operative procedure or later in one to several stages. Common types of breast reconstruction are:

- Breast expanders (saline or gel)
- Autologous reconstruction using the patient's own skin, fat, and muscle

Breast expanders are the most common method of breast reconstruction used today in the United States. A tissue expander is a balloon-like device with a resealable metal port that is placed under the pectoralis muscle. A small amount of normal saline is injected intraoperatively into the expander to partially inflate it. The patient then receives additional weekly saline injections for about 6 to 8 weeks until the expander is fully inflated. When full expansion is achieved, the tissue expander is then exchanged for a permanent implant during outpatient surgery. The permanent implant is filled with either saline or silicone gel. Despite earlier claims that silicone gel caused autoimmune diseases like lupus and arthritis, silicone implants have been safely used in the majority of women who choose this type of breast implant.

TABLE 73-4 EXAMPLES OF BREAST RECONSTRUCTION PROCEDURES

PROCEDURE	DESCRIPTION	PROCEDURE	DESCRIPTION
Implantation	An implant matching the size of the other breast is placed under the muscle on the operative side to create a breast mound.	Myocutaneous flaps	A flap of skin, fat, and muscle is transferred from the donor site to the operative area. The flap contains an appropriate amount of fat to match the other breast and is similar in appearance to breast tissue. A blood supply is established by reanastomosis of vessels from the operative area to those with the flap when possible. A new nipple may be created with tissue from areas such as the labia or upper, inner thigh. Nipples can also be created by tattooing.
			
			
Tissue expansion	A tissue expander is placed under the muscle and gradually expanded with saline to stretch the overlying skin and create a pocket. After several weeks, the tissue expander is exchanged for an implant.		
			

Autologous reconstruction using the patient's own skin, fat, and muscle is advantageous because the donor site tissue is similar in consistency to the natural breast. Therefore the results more closely resemble a real breast as compared with implant reconstruction. Flap donor sites include the latissimus dorsi flap (back muscle); transverse rectus abdominis myocutaneous flap, known as the *TRAM flap* (abdominal muscle); and the gluteal flap (buttock muscle). Reconstruction of the nipple-areola complex is the last stage in the reconstruction of the breast. If necessary, a new nipple may be created with other body tissue, such as from the labia, abdomen, or inner thigh.

Women who have had a mastectomy and breast reconstruction in one breast should have close surveillance breast

cancer screening in the contralateral (opposite) breast, including imaging with mammography or mammography and MRI. Mammography and MRI are not recommended to be routinely done in reconstructed breasts because most local recurrences of breast cancer in the residual tissue are palpable during clinical breast examination (Zakhireh et al., 2010). Nursing care of the woman who has undergone breast reconstruction is outlined in [Chart 73-3](#).

Adjuvant Therapy. The decision to follow the original surgical procedure with **adjuvant therapy** (in addition to surgery) for breast cancer is based on:

- The stage of the disease
- The patient's age and menopausal status
- Patient preferences

CHART 73-3 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Postoperative Care of the Patient After Breast Reconstruction

- Assess the incision and flap for signs of infection (excessive redness, drainage, odor) during dressing changes.
- Assess the incision and flap for signs of poor tissue perfusion (duskiness, decreased capillary refill) during dressing changes.
- Avoid pressure on the flap and suture lines by positioning the patient on her nonoperative side and avoiding tight clothing.
- Monitor and measure drainage in collection devices, such as Jackson-Pratt drains.
- Teach the patient to return to her usual activity level gradually and to avoid heavy lifting.
- Remind the patient to avoid sleeping in the prone position.
- Teach the patient to avoid participation in contact sports or other activities that could cause trauma to the chest.
- Teach the patient to minimize pressure on the breast during sexual activity.
- Remind the patient to refrain from driving until advised by the physician.
- Remind the patient to ask at the 6-week postoperative visit when full activity can be resumed.
- Reassure the patient that optimal appearance may not occur for 3 to 6 months postoperatively.
- If implants have been inserted, teach the proper method of breast massage to enhance expansion and prevent capsule formation (consult with the physician).
- Emphasize breast self-awareness; if the patient performs breast self-examination (BSE); review her technique
- Remind the patient of the importance of clinical breast examination and follow-up surveillance by her physician.

- Pathologic examination
- Hormone receptor status
- Presence of a known genetic predisposition

Adjuvant therapy for breast cancer consists of radiation therapy and drug therapy. The purpose of radiation therapy is to reduce the risk for local recurrence of breast cancer. Drug therapy includes chemotherapy, targeted therapy, and/or hormonal therapy. These drugs destroy breast cancer cells that may be present anywhere in the body. They are typically delivered after surgery for breast cancer, although **neoadjuvant** chemotherapy may be given to reduce the size of a tumor before surgery. Hormonal therapy is a chemoprevention option for high-risk women with a personal history of breast cancer.

Radiation Therapy. Radiation therapy is administered after breast-conserving surgery to kill breast cancer cells that may remain near the site of the original tumor. This therapy can be delivered to the whole breast or to only part of the breast. Until recently, the traditional method has been whole-breast irradiation delivered by external beam radiation over a period of 5 to 6 weeks. More recently, partial breast irradiation (PBI) has become an option for women with early-stage breast cancer. The use of brachytherapy (radioactive implants) has been increasing steadily, accounting for approximately 10% of radiation therapy administered to breast cancer patients (Smith et al., 2009). The advantage of this type of radiation is that it is delivered over a much shorter time interval, eliminating the need for daily trips for treatment. However, few long-term studies exist showing the effectiveness of brachytherapy compared with traditional radiation therapy. The

types of methods available for delivering *partial-breast irradiation* include:

- Interstitial brachytherapy, in which several catheters loaded with a radioactive source are inserted at the lumpectomy cavity and surrounding margin, is given over a period of 4 to 5 days.
- Balloon brachytherapy, also known as *MammoSite*, involves the use of a single balloon-tipped catheter that is surgically placed near the tumor bed. The catheter is loaded with a radiation source and inflated to conform to the total cavity. Ten total treatments are given, with at least 6 hours between each treatment.
- Intraoperative radiation therapy is the most accelerated form of partial breast irradiation. It utilizes a high single dose of radiation delivered during the lumpectomy surgery.

Nursing care for the patient undergoing radiation therapy includes patient education and side effect management. Skin changes are a major side effect during this therapy (see [Chapter 24](#)). If brachytherapy is planned, instruct patients about the procedure. Assure them that they will be radioactive only while the radiation source is dwelling inside the breast tissue.

! NURSING SAFETY PRIORITY

Action Alert

Teach women undergoing brachytherapy for breast cancer that radiation is contained in the temporary implant. The risk for others to be exposed to radiation is very small. Body fluids and items contacted by patients with brachytherapy are not radioactive. However, during the time the radiation is delivered, it is recommended they limit visitors, including pregnant women and children.

Chemotherapy. Chemotherapy for breast cancer is delivered systemically. Its purpose is to kill breast cancer cells that may have left the original tumor and moved to more distant sites. Chemotherapy is the standard of care for women with node-positive cancer or with a tumor larger than 1 cm (Maughan et al., 2010). As more scientific evidence emerges about the biology of tumors, it is hoped that the need for chemotherapy may be more specifically determined. Chemotherapy may be given before surgery to reduce the size of the tumor. [Table 73-5](#) lists common agents used in breast cancer and their mechanism of action. They are usually delivered in four to six courses of treatment. Combination regimens of chemotherapy have been demonstrated to be more effective than single-agent treatments. A common chemotherapy regimen for breast cancer treatment is Cytoxan, Adriamycin, and 5-FU (CAF), but several other types and combinations may be given. In early-stage breast cancer, chemotherapy regimens lower the risk for breast cancer recurrence. In advanced breast cancer, chemotherapy regimens reduce cancer size in many patients. Regimens that contain anthracyclines and taxanes have a small benefit over other chemotherapies for some types of breast cancer (Maughan et al., 2010).

Most chemotherapy for breast cancer is delivered via the central IV route such as an implantable venous access device (port-a-cath). Nurses must be very proficient in the preparation and administration of chemotherapy drugs and knowledgeable about various venous access devices. They must also be able to manage the distressing symptoms associated with

side effects of chemotherapy. [Chapter 24](#) discusses general nursing management of alopecia, nausea and vomiting, mucositis, and bone marrow suppression. Fatigue and sleep disturbance are often major concerns as side effects of chemotherapy.

! NURSING SAFETY PRIORITY

Action Alert

Teach patients undergoing chemotherapy with anthracyclines such as doxorubicin (Adriamycin) to be aware of cardiotoxic effects. Instruct them to report excessive fatigue, shortness of breath, chronic cough, and edema to the health care provider.

TABLE 73-5 DRUG THERAPY FOR BREAST CANCER

CATEGORY	MECHANISM OF ACTION	AGENTS
Chemotherapy		
Anthracyclines	Inhibit DNA synthesis in susceptible cells	Doxorubicin (Adriamycin) (A) Epirubicin (Ellence) (E)
Taxanes	Inhibit microtubule network in rapidly dividing cells	Docetaxel (Taxotere) (D) Paclitaxel (Taxol) (P) Paclitaxel, protein-bound (Abraxane)
Alkylating agents	Interfere with the replication of susceptible cells	Cyclophosphamide (Cytoxan) (C)
Antimetabolites	Inhibit DNA synthesis and cellular replication in rapidly dividing cells	Methotrexate (Mexate) (M) Fluorouracil (5-FU) (F) Capecitabine (Xeloda)
Targeted Therapy	Selectively target critical steps in the processes required for tumor growth, viability, or invasion	Trastuzumab (Herceptin)
Hormonal Therapy		
LH-RH agonists	Block release of LH and FSH, thereby preventing ovarian production of estrogen	Goserelin (Zoladex) Leuprolide (Lupron)
Selective estrogen receptor modulators (SERMs)	Bind to estrogen receptors; have both agonist and antagonist properties (selectively block action of estrogen in the breast but not in other organs)	Tamoxifen (Nolvadex) Raloxifene (Evista)
Aromatase inhibitors	Prevent conversion of adrenal and ovarian androgens to estrogens by inhibiting the aromatase enzyme	Anastrozole (Arimidex) Letrozole (Femara) Exemestane (Aromasin)
Estrogen receptor down-regulators	Induce degradation of estrogen receptor	Fulvestrant (Faslodex)

FSH, Follicle-stimulating hormone; LH, luteinizing hormone; LH-RH, luteinizing hormone-releasing hormone.

Chemotherapy is unpleasant and expensive and can have life-threatening short-term and long-term side effects. Because more women are living longer with breast cancer, long-term effects are increasingly emerging. Although targeted therapy is effective with fewer side effects, some side effects are nevertheless life threatening. For example, cardiac toxicity is a risk associated with the use of Herceptin, particularly when it is combined with other chemotherapy. Chemotherapy and ovarian suppression can result in infertility, a devastating effect for women of childbearing age. Hormonal therapy can result in long-term ill effects from bone loss. Discuss patient concerns, provide accurate information, and assist him or her in decision making.

Targeted Therapy. Targeted cancer therapies are drugs that target specific characteristics of cancer cells, such as a protein, an enzyme, or the formation of new blood vessels. The advantage of targeted therapy over traditional chemotherapy is that targeted therapy does not harm normal, healthy cells and therefore it has fewer side effects. The best known targeted therapy for breast cancer is the monoclonal antibody *trastuzumab* (Herceptin). This drug targets the *HER2/neu* gene product in breast cancer cells. The combination of trastuzumab and anthracyclines increases the risk for cardiotoxicity and must be used with caution (Maughan et al., 2010).

Bevacizumab (Avastin) inhibits tumor growth by targeting the growth factor *VEGF* and stopping the formation of new blood vessels that are needed to nourish the tumor. It is a drug used in several types of cancer. However, a recent review of bevacizumab by a panel of the Food and Drug Administration (FDA) showed there was no significant improvement in life span for patients with metastatic breast cancer and recommended against the use of bevacizumab in metastatic breast cancer (Food and Drug Administration [FDA], 2010).

Hormonal Therapy. The purpose of hormonal therapy is to reduce the estrogen available to breast tumors to stop or prevent their growth. *Premenopausal* women whose main estrogen source is the ovaries may benefit from *LH-RH agonists* that inhibit estrogen synthesis. These drugs include leuprolide (Lupron) and goserelin (Zoladex), which suppress the hypothalamus from making luteinizing hormone-releasing hormone (LH-RH). When LH-RH is inhibited, the ovaries do not produce estrogen. Although the suppression of ovarian function decreases breast cancer risk, the drastic drop in estrogen causes significant menopausal symptoms. Therefore the decision to use these drugs is not made lightly.

Selective estrogen receptor modulators (SERMs), on the other hand, do not affect ovarian function. Rather, they block the effect of estrogen in women who have estrogen receptor (ER)-positive breast cancer. SERMs are also used as chemoprevention in women at high risk for breast cancer and in women with advanced breast cancer. Tamoxifen is recommended to be taken for 5 years to achieve the best benefit for risk reduction. Common side effects of SERMs include hot flashes and weight gain. Rare but serious side effects of these drugs include endometrial cancer and thromboembolic events.

Aromatase inhibitors (AIs) are used in *postmenopausal* women whose main source of estrogen is not the ovaries but, rather, body fat. AIs reduce estrogen levels by inhibiting the conversion of androgen to estrogen through the action of the

enzyme *aromatase*. AIs are beneficial when given to postmenopausal women after 5 years of treatment with tamoxifen. A major side effect of the AIs, not seen with tamoxifen, is loss of bone density. Women taking AIs are candidates for bone-strengthening drugs and must be closely monitored for osteoporosis. Fulvestrant (Faslodex), a second-line hormonal therapy for postmenopausal women with advanced breast cancer, is used after other hormonal treatments have stopped working.

Stem Cell Transplantation. Autologous or allogeneic stem cell transplantation is an option for patients with a high risk for recurrence or who have advanced disease. **Autologous** bone marrow transplantation (taken from the patient's bone marrow), peripheral blood stem cell transplantation (taken from circulating blood), or **allogeneic** bone marrow transplantation (taken from a healthy donor's bone marrow or peripheral blood) is performed as a means of rescue therapy after very high doses of chemotherapy. The general care of the patient undergoing bone marrow or stem cell transplantation is discussed in [Chapter 42](#).

DECISION-MAKING CHALLENGE

Patient-Centered Care; Safety

A 39-year-old African-American woman who is an executive for a major technology business is diagnosed with breast cancer and scheduled for a lumpectomy and radiation therapy. She tells you that she regrets that her life has not allowed time for having children. She is currently single but has a male partner whom she has been dating for 3 years. After surgery, she tells the nurse that she plans on going back to work in a week or two but that she is very anxious about her future.

1. What evidence-based risk factors does this patient have?
2. What discharge instructions will you provide for her and why?
3. What will you teach the patient about radiation therapy to maintain her safety?
4. How might you help allay the patient's anxiety?

Community-Based Care

Home Care Management

In collaboration with the case manager, make the appropriate referrals for care after discharge. Preoperative teaching and arrangements for home care management and referrals (Reach to Recovery, social services, home care) can be started before surgery or other treatment.

The patient who has undergone breast surgery can be discharged to the home setting unless other physical disabilities exist. Some are discharged the day after surgery with Jackson-Pratt or other types of drains in place. Many patients are discharged to home on the day of surgery. Older adults should not be sent home without a family member or friend who can stay with them for 1 to 2 days. These patients may need some assistance at home with drain care, dressings, and ADLs because of pain and impaired range of motion of the affected arm. Summaries of continuing care instructions are given in [Charts 73-4 and 73-5](#).

Teach patients that activities involving stretching or reaching for heavy objects should be avoided temporarily. This restriction can be discussed with a family member or significant other who can perform these tasks or place the objects within easy reach.

Teaching for Self-Management

The teaching plan for the patient after surgery includes:

- Measures to improve body image
- Information about interpersonal relationships and roles
- Exercises to regain full range of motion
- Measures to prevent infection of the incision
- Measures to avoid lymphedema
- Measures to avoid injury, infection, and swelling of the affected arm
- Care of the incision and drainage device

Teach incisional care to the patient, family, and/or other caregiver. The patient may wear a light dressing to prevent irritation. Explain that no lotions or ointments should be used on the area and that the use of deodorant under the affected arm should be avoided until healing is complete. Although swelling and redness of the scar itself are normal for the first few weeks, swelling, redness, increased heat, and tenderness of the

CHART 73-4 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Recovery from Breast Cancer Surgery

- There may be a dry gauze dressing over the incision when you leave the hospital. You may change this dressing if it becomes soiled.
- A small, dry dressing will be around the site where a drain is placed. Often there is some leakage of fluid around the drain. Check the gauze dressing for drainage, and change it if it becomes soiled. Some leakage is normal, but if the dressing becomes soaked more than once a day, call your health care provider.
- You have been taught how to empty the reservoir from your drain and how to measure the volume of drainage. You should empty the drain twice a day and record the measurements.
- Drains are generally removed when drainage is less than 25 mL in 24 hours.
- Drains are often removed at the same time as the stitches or staples, generally 7 to 10 days (could be as long as 3 weeks if needed) after surgery.
- You may take sponge baths or tub baths, making certain that the area of the drain and incision stays dry. You may shower after the stitches, staples, and drains are removed.
- You can begin using your arm for normal activities, such as eating or combing your hair. Exercises involving the wrist, hand, and elbow, such as flexing your fingers, circular wrist motions, and touching your hand to your shoulder, are very good. You can usually resume more strenuous exercises after the drains have been removed.
- You can expect some discomfort or mild pain after surgery, but within 4 to 5 days, most women have no need for pain medication or require medication only at bedtime.
- Numbness in the area of the surgery and along the inner side of the arm from the armpit to the elbow occurs in almost all women. It is the injury to the nerves that causes sensation to the skin in those areas. Women have described sensations of heaviness, pain, tingling, burning, and "pins and needles." Neuropathic pain is sometimes relieved by gabapentin (Neurontin). These sensations change over the months and usually resolve by 1 year.
- Pamphlets on exercises, hand and arm care, and general facts about breast cancer are available from us or from a volunteer visitor. The American Cancer Society has volunteers who have had surgery similar to yours and are available to visit you.

CHART 73-5 HOME CARE ASSESSMENT

Patients Recovering from Breast Cancer Surgery

Assess cardiovascular, respiratory, and urinary status:

- Vital signs
- Lung sounds
- Urine output patterns

Assess for pain and effectiveness of analgesics.

Assess dressing and incision site:

- Excess drainage
- Manifestations of infection
- Wound healing
- Intact staples

Assess drain and site:

- Drainage around drain site and in drain
- Color and amount of drainage
- Manifestations of infection

Review patient's recordings of drainage.

Evaluate patient's ability to care for and empty drain.

Assess status of affected extremity:

- Range of motion
- Ability to perform exercise regimen
- Lymphedema

Assess nutritional status:

- Food and fluid intake
- Presence of nausea and vomiting
- Bowel sounds

Assess functional ability:

- Activities of daily living
- Mobility and ambulation

Assess home environment:

- Safety
- Structural barriers

Assess patient's compliance and knowledge of illness and treatment plan:

- Follow-up appointment with surgeon
- Manifestations to report to health care provider
- Hand and arm care guidelines
- Referral to Reach to Recovery

Assess patient and caregiver coping skills:

- Determine if patient and/or caregiver has looked at incision site.
- Assess their reaction to incision site.

surrounding area indicate infection and should be reported to the surgeon immediately. If a lymph node dissection was performed, instruct the patient to elevate the affected arm on a pillow for at least 30 minutes a day for the first 6 months. Ask the patient to have someone bring a loose-fitting, non-wire bra or camisole for her to try before discharge with a soft, cotton-filled or polyester fiber-filled form supplied by the hospital or by Reach to Recovery. The patient wears this form until the incision is completely healed and the health care provider approves the fitting of a more sophisticated prosthesis, usually 6 to 8 weeks after discharge. Encourage the patient to dress in loose-fitting street clothes at home, not pajamas, to further enhance a positive self-image.

Teach the patient to continue performing the exercises that began in the hospital. Active range-of-motion exercises should begin 1 week after surgery or when sutures and drains are removed. Emphasize that reaching and stretching exercises should continue only to the point of pain or pulling, never beyond that. ENCORE, a YWCA program, is appropriate for women as early as 3 weeks after surgery and includes exercise to music, exercise in water, and psychological support. Before discharge, the surgeon may prescribe precautions or

limitations specific to plans for future procedures, such as reconstruction.

Lymphedema, an abnormal accumulation of protein fluid in the subcutaneous tissue of the affected limb after a mastectomy, is a commonly overlooked topic in health teaching. Risk factors include injury or infection of the extremity, obesity, presence of extensive axillary disease, and radiation treatment. Once it develops, it can be very difficult to manage, and *lifelong measures must be taken to prevent it*. Nurses play a vital role in educating patients about this complication (Fu et al., 2008).

! NURSING SAFETY PRIORITY**Action Alert**

Provide information needed to help the patient avoid infection and subsequent lymphedema of the affected arm after the mastectomy. Teach the importance of avoiding having blood pressure measurements taken on, having injections in, or having blood drawn from the arm on the side of the mastectomy. Instruct the patient to wear a mitt when using the oven, wear gloves when gardening, and treat cuts and scrapes appropriately. If lymphedema occurs, early intervention provides the best chance for control. The arm should be elevated when possible and special attention paid to the special precautions. A referral to a lymphedema specialist may be necessary for the patient to be fitted for a compression sleeve and/or glove, to be taught exercises and manual lymph drainage, and to discuss ways to modify daily activities to avoid worsening the problem. Management is directed toward measures that promote drainage of the affected arm. Teach patients, especially those who have had axillary lymph nodes removed, that measures to prevent lymphedema are lifelong and include avoiding trauma to the arm on the side of the mastectomy.

Psychosocial Preparation

Concerns about appearance after surgery are common and are often a threat to the patient's self-concept as a woman. Before breast surgery, the woman and her partner can benefit from an explanation of the expected postoperative appearance. After a modified radical mastectomy, the chest wall is fairly smooth and has a horizontal incision from the axilla to the midchest area. After breast-conserving surgery, scars vary according to the amount of breast tissue removed. Women are sometimes shown pictures of post-mastectomy reconstruction but are disappointed with their own results. Emphasize that scars will fade and edema will lessen with time. Scars may be red and raised at first, but these features lessen in the first few months. After surgery, encourage the woman to look at her incision when she is ready. Do not push her to accept this body image change immediately.

Much of one's body image is a reflection of how others respond. Therefore the response of the patient's family or partner to the surgery is crucial in determining the effect on self-concept. These people may also need the support of the nurse. They may have concerns about their ability to accept the changes and need to discuss these feelings with an objective listener. They may also need help with communicating their feelings, both negative and positive, with their loved one. Involving them in teaching may also help reinforce learning and increase retention.

Discuss sexual concerns before discharge. Most surgeons recommend avoiding sexual intercourse for 4 to 6 weeks. Patients may prefer to lay a pillow over the surgical site or to wear a bra, camisole, or T-shirt to prevent contact with the

surgical site during intercourse. He or she may be embarrassed to discuss the topic of *sexuality*. Be sensitive to possible concerns, and approach the subject first.

For young women, issues related to childbearing may be a concern. Chemotherapy and radiation are considered serious teratogenic (birth defect–causing) agents. Advise sexually active patients receiving chemotherapy or radiotherapy to use birth control during therapy. The method and length of birth control should be discussed with the health care provider.

Health Care Resources

Resources available to the patient after discharge include personal support and community programs. After discharge, the spouse or partner may need help in planning support for home responsibilities. For example, a partner who may be assuming additional duties at home and work may feel stressed. Discussing the need for ongoing emotional support is also beneficial to both the patient and partner. Leaving the hospital and appearing normal do not end the anxiety and fear. Identifying a support person with whom the patient or couple can explore these feelings and discussing the need to ventilate feelings enhance personal and family recovery.

Numerous support and educational resources are available to those diagnosed with breast cancer. Nurses must provide

accurate and current information to patients who may have obtained inaccurate information from various media. There are over two million breast cancer survivors in the United States, and many men and women are active in breast cancer support and advocacy organizations. National breast cancer organizations are accessible online, and many of them have local affiliates. Examples of such organizations are Susan G. Komen for the Cure, the National Breast Cancer Coalition, Y-Me, Sisters Network, Young Survival Coalition, and Pink Ribbon Girls. Also, local support groups can be accessed through the health care provider, the local hospital, wellness centers, home care agencies, or by word of mouth. The American Cancer Society (ACS) (www.cancer.org) is a good resource for information and support.

EVALUATION: OUTCOMES

Evaluate the care of the patient with breast cancer based on the identified priority patient problems. The expected outcomes include that he or she will:

- Be able to cope with the diagnosis by being knowledgeable, supported, and actively involved in decision making
- Remain free of metastasis

NURSING CONCEPT REVIEW

What might you NOTICE if a patient is experiencing impaired sexuality as a result of breast cancer or other disorder?

- Breast swelling or lump (with or without pain)
- Discharge from nipple(s)
- Skin dimpling or orange peel appearance
- Asymmetric breast tissue
- Very large or very small breasts
- Skin redness and warmth

What should you INTERPRET and how should you RESPOND to a patient having impaired sexuality as a result of breast cancer or other disorder?

Perform and interpret physical assessment, including:

- Take a thorough patient and family history.
- Examine each breast, comparing sides, and document.
- Assess pain, and document.
- Assess psychosocial reaction to the breast changes.

Respond by:

- Checking recent mammogram test or other imaging assessment results
- Acknowledging patient's concerns about body image and sexuality changes
- Asking the patient about resources for support that have been used in the past for coping with crisis
- Preparing the patient for testing and possible biopsy
- Listening to the patient's concerns in a nonjudgmental manner

On what should you REFLECT?

- Consider what health care resources (team members) the patient and family will need throughout disease management.
- Think about what other community resources the patient and family will need.
- Observe the patient's progress in adapting to body image changes.

GET READY FOR THE NCLEX® EXAMINATION!**KEY POINTS**

Review these Key Points for each NCLEX Examination Client Needs Category.

Safe and Effective Care Environment

- In collaboration with the health care team, identify community resources for patients with breast cancer, including Reach to Recovery of the American Cancer Society.

Health Promotion and Maintenance

- Identify patients at high risk for breast cancer, especially women with family history of breast cancer; those who have had early menarche, late menopause, or first pregnancy after 30 years of age; or those who are nullipara.
- Reinforce options available to women who are high risk for breast cancer, including close surveillance and prophylactic surgery.
- Teach women to become self-aware of breasts and any breast changes; teach breast self-examination (BSE) to women who choose this method of breast self-awareness.
- Encourage women to have screening mammography according to recommended guidelines. Baseline screening should begin at 40 years of age and continue yearly. In high-risk women, screening should be started earlier.
- Encourage women to have clinical breast examination (CBE) according to recommended guidelines.

Psychosocial Integrity

- Assess patients' reactions to the diagnosis of breast cancer and the effect of breast cancer treatment on their body image and sexuality.
- Identify resources that facilitate their grief work and coping skills.
- Allow patients opportunities to express feelings of grief, fear, and anxiety.

- Teach women ways to minimize surgical area deformity and enhance body image, such as use of a breast prosthesis or the option of breast reconstruction.
- Address the reactions of family and significant others to the diagnosis of breast cancer; provide support and education.

Physiological Integrity

- Assess benign lumps as mobile and round or oval; assess possible malignant lumps as fixed and irregularly shaped, often in the upper outer breast quadrant.
- A breast reduction is an option for women with very large, heavy breasts to promote comfort.
- A breast augmentation is done for either small breasts or for reconstruction after breast removal.
- After breast cancer surgery, assess vital signs, dressings, drainage tubes, and amount of drainage.
- Notify the health care team that the arm of the surgical mastectomy side should not be used for blood pressures, blood drawing, or injections.
- Assess the return of arm and shoulder mobility after breast surgery and axillary dissection.
- Assess for the presence of lymphedema, and assist the patient to perform therapeutic measures to reduce lymphedema in the affected arm.
- Teach the patient measures to prevent lymphedema after axillary node dissection.
- Observe for and report other complications of breast cancer surgery or breast reconstruction, especially infection and inadequate vascular perfusion.
- After an axillary lymph node dissection, elevate the affected arm on a pillow.
- Radiation and drug therapy are used most often as adjuvant therapy after breast surgery but may be used before surgery to shrink the tumor.

Care of Patients with Gynecologic Problems

Donna D. Ignatavicius

Concept Map Creator

Key Points

Review Questions for the NCLEX® Examination

LEARNING OUTCOMES

Safe and Effective Care Environment

1. Collaborate with members of the health care team when caring for patients with gynecologic cancers.

Health Promotion and Maintenance

2. Identify the risk factors for gynecologic cancers.
3. Provide health teaching on community resources for patients with gynecologic health problems.
4. Describe evidence-based health promotion and maintenance measures to help prevent or early-detect gynecologic cancers.

Psychosocial Integrity

5. Explain the psychosocial needs of patients with gynecologic health problems, including their effect on sexuality.
6. Discuss ways to help patients adapt to physical changes, including impaired sexuality, caused by gynecologic problems and their treatment.

Physiological Integrity

7. Compare the pathophysiology, manifestations, and treatments of common menstrual cycle disorders.
8. Describe the mechanisms of action, side effects, and nursing implications of drug therapy for endometriosis.
9. Develop a teaching plan for a patient with a vaginal inflammation or infection.
10. Discuss common assessment findings associated with menopause.
11. Prioritize care after surgery for the woman undergoing an anterior and/or posterior repair.
12. Develop a plan of care for a patient undergoing a hysterectomy.
13. Explain the purpose of radiation and chemotherapy for patients with gynecologic cancers.
14. Provide information about complementary and alternative therapies.
15. Develop a community-based plan of care for patients with gynecologic cancers.

The most common gynecologic manifestations are pain, vaginal discharge, and bleeding. Some patients also have urinary symptoms associated with their gynecologic problem. Women are often hesitant to seek medical attention for these problems because of fear of a life-threatening disease diagnosis or concern about privacy and dignity. Be sensitive to the woman's concerns and encourage discussion about menstrual or other reproductive problems. Teach women about their bodies, and help them recognize when professional help should be sought. Teach them how to make informed decisions about treatments. Assess the effects of gynecologic

disorders on *sexuality* in any setting. These health problems often impair sexual function and therefore can affect the woman's relationship with her partner. Remember that *sexuality* affects a woman's sense of being, self-esteem, and body image.

ENDOMETRIOSIS

Pathophysiology

Endometriosis is endometrial (inner uterine) tissue implantation *outside* the uterine cavity. The tissue typically appears

FIG. 74-1 Common sites of endometriosis.

on the ovaries and the cul-de-sac (posterior rectovaginal wall) and less commonly on other pelvic organs and structures (Fig. 74-1). A “chocolate” cyst is an area of endometriosis on an ovary. The disease affects millions of women in the United States and Canada.

Endometriosis responds to cyclic hormonal stimulation just as if it were in the uterus. Monthly cyclic bleeding occurs at the **ectopic** (out of place) site of implantation, which irritates and scars the surrounding tissue. Scarring can lead to adhesions, causing infertility (inability to become pregnant). Endometriosis progresses slowly and regresses during pregnancy and at menopause. Rarely does it become cancerous.

The cause of endometriosis is unknown. One theory is that the endometrial tissue migrates directly through the fallopian tubes during menses. The tissue then implants on pelvic structures or distant organs such as lungs or heart. The formation theory suggests that endometrial tissue develops outside the uterus as a birth defect. Other theories focus on immune, genetic, and environmental factors (e.g., exposure to dioxin, a toxic chemical). Many women with endometriosis have allergies and chemical sensitivities.

The disorder is most often found in women during their reproductive years, but it can affect women into their 80s. The prevalence among infertile women is higher than it is for women who are fertile. It is also common in those whose mothers had endometriosis.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Collect a detailed history, including the woman’s menstrual history, sexual history, and bleeding characteristics. *Pain is the most common symptom of endometriosis.* The pain usually peaks just before the menstrual flow. It is usually located in the lower abdomen, causing many women to feel a sense of rectal pressure. The degree of pain is not related to the extent of the endometriosis but to the site. Often, women with minimal disease have more severe pain than do women with extensive disease. Other manifestations include **dyspareunia**

(painful sexual intercourse), painful defecation, low backache, and infertility. GI disturbances such as nausea and diarrhea are also common. Always ask about current or past physical or sexual abuse.

A pelvic examination may reveal pelvic tenderness, tender nodules in the posterior vagina, and limited movement of the uterus. Psychosocial assessment may reveal anxiety because of uncertainty about the diagnosis. The woman may also have concerns about her self-concept if she is infertile but wants to become pregnant.

Diagnostic studies include tests to rule out pelvic inflammatory disease caused by chlamydia or gonorrhea. Serum cancer antigen CA-125 helps screen for ovarian cancer but also may be positive in women with endometriosis. Transvaginal ultrasound is used to differentiate pelvic masses that might be mistaken for endometriosis.

INTERVENTIONS

Hormonal and surgical management may be used, depending on the symptoms, the extent of disease, and the woman’s desire for childbearing. Collaborative care is aimed at:

- Reducing pain
- Restoring sexual function
- Alleviating anxiety related to the disease and the uncertainty of the diagnosis
- Educating the patient about the disease and its treatment
- Alleviating fear related to the possibility of laparoscopy or surgery
- Preventing self-esteem disturbance related to infertility

Nonsurgical Management

Several resources, such as the Endometriosis Association (www.endometriosisassn.org) and RESOLVE (an organization for infertile couples) (www.resolve.org), offer information on endometriosis that is helpful for patients and caregivers.

Disease management depends of the patient’s symptoms, severity, and preference for treatment. Menstrual cycle control using oral contraceptives or progestins, such as oral medroxyprogesterone acetate (Provera, Medroxyhexal, Alti-MPA ) and norethindrone acetate (Aygestin, Norlutate ) may be prescribed. Injectable forms of progestins, such as medroxyprogesterone (Depo-Provera), may be more convenient because these drugs are taken every 2 weeks or monthly.

Continuous low-level heat using wearable heat packs may provide temporary pain relief. Relaxation techniques, yoga, massage, and biofeedback may decrease muscle tissue hypoxia and hypertonicity and relieve ischemia by increasing blood flow to the affected areas. Calcium and magnesium may also relieve muscle cramping for some patients.

Surgical Management

Surgical management of endometriosis for a woman who wants to remain fertile is the laparoscopic removal of endometrial implants and adhesions in a same-day surgical setting. Chapter 18 describes the general postoperative care for patients having surgery. The surgeon may use a laser to treat endometriosis by vaporizing adhesions and endometrial implants. Teach patients that temporary postoperative pain from carbon dioxide can occur in the shoulders and chest.

TABLE 74-1 RISK FACTORS FOR DYSFUNCTIONAL UTERINE BLEEDING

- Obesity
- Extreme weight loss or gain
- Age older than 40 years
- High stress levels
- Polycystic ovary disease
- Long-term drug use (e.g., oral contraceptives)
- Excessive exercise

DYSFUNCTIONAL UTERINE BLEEDING

Pathophysiology

Dysfunctional uterine bleeding (DUB) is excessive and frequent bleeding (more than every 21 days). It is a diagnosis of exclusion, made after ruling out anatomic or systemic conditions such as drug therapy or disease. DUB occurs most often at the beginning or end of a woman's reproductive years—when ovulation is becoming established or when it is becoming irregular at or after menopause.

Normally the menstrual cycle is a series of delicately timed hormonal events regulated by hypothalamic, pituitary, ovarian, and uterine functions. **Menses**, the sloughing of the endometrial lining, is an expected result. DUB occurs when there is a hormonal imbalance. Generally, it happens when the ovaries fail to ovulate. This decreases progesterone production, which is needed to mature the uterine lining and prevent overgrowth. Without progesterone, prolonged estrogen stimulation causes the endometrium to grow past its hormonal support, causing disordered shedding of uterine lining. Most cases of DUB are classified into two types: anovulatory DUB (most common) and ovulatory DUB (Ayers & Montgomery, 2009). Common risk factors for DUB during the reproductive years are listed in Table 74-1.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

When interviewing a woman with DUB, take a complete menstrual history. Ask about illnesses, changes in weight or nutritional intake, exercise, drug ingestion, and whether she has pain.

Assess for symptoms of anemia or systemic disease, such as:

- Renal or hepatic disease
- Abnormal weight
- Signs of hormonal dysfunction, such as thyroid enlargement or male hair pattern
- Evidence of abdominal pain or masses

The health care provider inspects the external genitalia and does a bimanual pelvic examination, Papanicolaou test, and rectal examination to identify infections, lesions, or tenderness. Vaginal specimens are also tested for sexually transmitted diseases (STDs), such as that caused by chlamydia. Women at high risk for endometrial cancer should also have an endometrial biopsy. Risk factors are described later in this chapter.

A complete blood count determines if the patient is anemic. Depending on the patient's history and physical examination, thyroid-stimulating hormone and reproductive hormone levels may be evaluated.

Transvaginal ultrasound may reveal **leiomyomas** (fibroids) and measure an excessively thick endometrium. *Sonohysterography* uses vaginal ultrasound to visualize the uterus after 5 to 10 mL of sterile saline is infused through the cervix, thus outlining the inner uterine cavity.

INTERVENTIONS

Management of the patient often includes nonsurgical and surgical interventions. When nonsurgical treatment is not effective, surgery may be performed.

Nonsurgical Management

As with endometriosis, hormone manipulation is usually the treatment of choice for women with anovulatory DUB. The drugs used depend on the severity of bleeding and age of the patient. Progestin or combination hormone therapy (estrogen and progestin) is indicated when bleeding is heavy and acute. For nonemergent bleeding, contraceptives (oral or patch) provide the progestin (artificial progesterone) needed to stabilize the endometrial lining. Progestin-only pills (e.g., norethindrone [Aygestin, Norlutate ) or long-acting progestins (e.g., injectable medroxyprogesterone acetate [Depo-Provera]) are preferable for women older than 35 years who smoke or are at risk for thrombophlebitis. Some cases are managed with injectable leuprolide (Lupron), a gonadotropin-releasing (GR) hormone analog, to reduce the follicle-stimulating and luteinizing hormone levels to cause amenorrhea. This drug has many potent side and adverse effects and is not used as frequently today.

Explain the desired effects and the side effects of these drugs, and evaluate the woman's knowledge of the effects, dosage, and schedule. Be sure to remind her to take the drug exactly as prescribed and to not skip a dose or run out of it. If bleeding worsens, teach the patient to call her health care provider immediately.

Surgical Management

Removal of the built-up uterine lining, called **endometrial ablation**, stops the blood flow to fibroids that are causing excessive bleeding. This is a safe alternative for women who do not respond to medical management. Other invasive options include uterine artery embolization, dilation and curettage, and hysterectomy. A hysterectomy is performed only after other treatments have failed. (Hysterectomy is discussed under Surgical Management on p. 1619 of the Uterine Leiomyoma section.)

VULVOVAGINITIS

Pathophysiology

Vaginal discharge and itching are two problems experienced by most women at some time in their lives. Women can suffer vaginal infections from both sexually and non-sexually transmitted sources. Gonorrhea, syphilis, chlamydia, and herpes simplex virus are sexually transmitted diseases (STDs) discussed in Chapter 76.

Vulvovaginitis is inflammation of the lower genital tract resulting from a disturbance of the balance of hormones and flora in the vagina and vulva. It may be characterized by itching, change in vaginal discharge, odor, or lesions. The most common causes include:

- Fungal (yeast) infections (*Candida albicans*)
- Bacterial vaginosis
- STDs (*Trichomonas vaginalis*)
- Postmenopausal vaginal atrophy
- Changes in the normal flora or pH (from douching)
- Chemical irritant or allergens (vaginal spray, fabric dyes, detergent) or foreign body (tampon)
- Drugs, especially antibiotics
- Immunosuppression from diabetes or human immune deficiency virus (HIV)

Primary infections that affect the vulva include *herpes genitalis* and *condylomata acuminata* (human papilloma virus, venereal warts) (see [Chapter 76](#)). Secondary infections of the vulva are caused by organisms responsible for the many types of vaginitis, including *candidiasis*. Pediculosis pubis (crab lice) and scabies (itch mite) are common parasitic infestations of the skin of the vulva. Other causes of vulvitis include:

- Atrophic vaginitis
- Lichen planus (thickened, leathery skin from scratching)
- Vulvar leukoplakia (postmenopausal atrophy and thickening of vulvar tissues)
- Vulvar cancer
- Urinary incontinence

Some women may have an *itch-scratch-itch cycle*, in which the itching leads to scratching, which causes excoriation that then must heal. As healing takes place, itching occurs again. If the cycle is not interrupted, the chronic scratching may lead to the white, thickened skin of lichen planus. This dry, leathery skin cracks easily, increasing the woman's risk for infection.

PATIENT-CENTERED COLLABORATIVE CARE

Assess for vulvovaginitis by asking questions about the symptoms, assisting with a pelvic examination, and obtaining vaginal smears for laboratory testing. Inquire about symptoms of itching and burning sensation. **Erythema** (redness), edema, and superficial skin ulcers also may be present. Use a nonjudgmental approach and provide reassurance during the assessment because the patient may be embarrassed or afraid to discuss her symptoms. Encourage her to talk about her problem and its effect on her sexual health.

Interventions for vulvovaginitis depend on the causes and the specific vaginal infection. Proper health habits can benefit treatment. Instruct the patient to get enough rest and sleep, observe good dietary habits, exercise regularly, and use good personal hygiene. Teach her about how to manage her infection ([Chart 74-1](#)). [Chart 74-2](#) outlines measures to help prevent further infections.

Nursing interventions to relieve itching include applying wet compresses, sitz baths for 30 minutes several times a day, and using topical drugs such as estrogens and lidocaine. Encourage the removal of any irritant or allergen, such as changing detergents.

Treatment of pediculosis and scabies is used if needed and includes:

- Applying lindane (Kwell, Kwellada ) lotion, shampoo, or cream to the affected area as directed
- Cleaning affected clothes, bedding, and towels
- Disinfecting the home environment (lice cannot live for more than 24 hours away from the body)

CHART 74-1 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Vaginal Infections

- Your risk for getting vaginal infections increases if you have sex with more than one person.
- When you have a vaginal infection, do not have sexual intercourse, if possible, or at least make sure that your partner wears a condom.
- Sexual partners may need to be treated for infection.
- The only way to identify what infection you have is to be examined by a health care provider and to get the results of laboratory tests.
- Take your medicine as prescribed, not just until your symptoms go away.

CHART 74-2 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Prevention of Vulvovaginitis

- Wear cotton underwear.
- Avoid wearing tight clothing, such as pantyhose or tight jeans, because they can cause chafing. You can also get hot and sweaty, which can cause an infection.
- Always wipe front to back after having a bowel movement or urinating.
- During bath or shower, cleanse inner labial mucosa with water, not soap.
- Do not douche or use feminine hygiene sprays.
- If your sexual partner has an infection of the sex organs, do not have intercourse with him or her until he or she has been treated.
- You are more likely to get an infection if you are pregnant, have diabetes, take oral contraceptive drugs, or are menopausal.
- Practice vulvar self-examination monthly.

NCLEX EXAMINATION CHALLENGE

Health Promotion and Maintenance

A client reports new onset of vulvar burning, redness, and pruritus. Which of these questions by the nurse would be the most appropriate?

- "Have you recently changed clothes detergents?"
- "Have you seen your health care provider about this problem?"
- "Have you had your HPV vaccine yet?"
- "Does this problem run in your family?"

TOXIC SHOCK SYNDROME

Pathophysiology

Toxic shock syndrome (TSS) was first recognized in 1980 when it was found to be related to menstruation and tampon use. Other conditions associated with TSS include surgical wound infection, nonsurgical infections, and gynecologic surgeries. Use of internal contraceptives has also been linked to this health problem.

In infection related to menstruation, menstrual blood provides a growth medium for *Staphylococcus aureus* (or, less frequently, *Streptococcus*). Exotoxins produced from the bacteria cross the vaginal mucosa to the bloodstream via micro-abrasions from tampon insertion or prolonged use. A small number of TSS cases are fatal. Extensive public education

CHART 74-3 KEY FEATURES

Toxic Shock Syndrome

- Fever (temperature $>102^{\circ}\text{F}$ [38.9°C])
- Diffuse rash resembling sunburn
- Peeling of skin—primarily the soles of the feet and the palms of the hands—1 to 2 wk after onset of the illness
- Hypotension (systolic blood pressure $<90\text{ mm Hg}$ or orthostatic syncope)
- Involvement of three or more of these:
 - Gastrointestinal system: vomiting, diarrhea at the onset of the syndrome
 - Musculoskeletal system: severe aching or a serum creatinine phosphatase level twice the normal level
 - Respiratory system: acute respiratory distress syndrome (ARDS)
 - Renal/urinary system: decreased urine output, pyuria
 - Cardiovascular system: decreased left ventricular contractility; ischemic changes shown on the electrocardiogram
 - Liver: total bilirubin, aspartate aminotransferase (serum glutamic-oxaloacetic transaminase), and alanine aminotransferase (serum glutamic-pyruvic transaminase) levels elevated; jaundice; disseminated intravascular coagulation (DIC)
 - Hematologic system: platelet levels below normal
 - Central nervous system: disorientation, altered consciousness in the absence of fever or hypertension
 - Mucous membranes: hyperemia of the vaginal walls, the throat, or the conjunctiva of the eye
- Negative results for Rocky Mountain spotted fever, measles, and scarlet fever and for throat, blood, and cerebrospinal fluid cultures
- Positive culture for *Staphylococcus aureus* from blood, urine, or stool

has led to a decreased number of women having the infection.

PATIENT-CENTERED COLLABORATIVE CARE

Within 24 hours of contact with the causative agent, the abrupt onset of a high fever, along with headache, flu-like symptoms, and severe hypotension with fainting, is often present. A sunburn-like rash with broken capillaries in the eyes and skin is another warning sign of TSS. Because not all women have all these manifestations, the criteria established by the Centers for Disease Control and Prevention (CDC) are used to verify cases (Chart 74-3). Educate all women on the prevention of TSS (Chart 74-4).

Treatment includes removal of the infection source, such as a tampon; restoring fluid and electrolyte balance; drugs to manage hypotension; and IV antibiotics. Other measures may include transfusions to reverse low platelet counts and corticosteroids to treat skin changes.

PELVIC ORGAN PROLAPSE

Pathophysiology

The pelvic organs are supported by a sling of muscles and tendons, which sometimes become weak and no longer able to hold an organ in place. **Uterine prolapse**, the most common type of **pelvic organ prolapse (POP)**, can be caused by neuromuscular damage of childbirth; increased intra-abdominal

CHART 74-4 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Prevention of Toxic Shock Syndrome

- Wash your hands before inserting a tampon.
- Do not use a tampon if it is dirty.
- Insert the tampon carefully to avoid injuring the delicate tissue in your vagina.
- Change your tampon every 3 to 6 hours.
- Do not use superabsorbent tampons.
- Use sanitary napkins at night.
- Call your health care provider if you suddenly experience a high temperature, vomiting, or diarrhea.
- Do not use tampons at all if you have had toxic shock syndrome.
- Not using tampons almost guarantees that you will not get toxic shock syndrome.

pressure related to pregnancy, obesity, or physical exertion; or weakening of pelvic support due to decreased estrogen. The stages of uterine prolapse are described by the degree of descent of the uterus (Fig. 74-2) through the pelvic floor.

Whenever the uterus is displaced, other structures such as the bladder, rectum, and small intestine can protrude through the vaginal walls (Fig. 74-3). A **cystocele** is a protrusion of the bladder through the vaginal wall (urinary bladder prolapse), which can lead to stress urinary incontinence (SUI) and urinary tract infections (UTIs). A **rectocele** is a protrusion of the rectum through a weakened vaginal wall (rectal prolapse).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Assessment findings for patients with a suspected uterine prolapse include the patient's feeling as if "something is falling out," dyspareunia (painful intercourse), backache, and a feeling of heaviness or pressure in the pelvis. A pelvic examination may reveal a protrusion of the cervix when the woman is asked to bear down. Listen to her concerns, and note signs of depression from having long-term symptoms.

Ask the patient about manifestations that may indicate that she has a **cystocele**. These signs and symptoms may include:

- Difficulty in emptying the bladder
- Urinary frequency and urgency
- Urinary tract infection
- **Stress urinary incontinence (SUI)** (loss of urine during activities that increase intra-abdominal pressure, such as laughing, coughing, sneezing, or lifting heavy objects)

A pelvic examination reveals a large bulge of the anterior vaginal wall when the woman is asked to bear down. Diagnostic tests include cystography (to show the presence of bladder herniation), measurement of residual urine by bladder ultrasound, and urine culture and sensitivity testing. Radiographic imaging of urinary anatomy and voiding function is useful in determining the degree of cystocele.

Rectocele assessment usually includes symptoms of constipation, hemorrhoids, fecal impaction, and feelings of rectal or vaginal fullness. A vaginal and rectal examination may show a bulge of the posterior vaginal wall when the woman is asked to bear down.

INTERVENTIONS

Interventions are based on the degree of the POP. Conservative treatment is preferred over surgical treatment when possible.

Nonsurgical Management

Teach women to improve pelvic support and tone via pelvic floor muscle exercises (PFMEs, or Kegel exercises). Space-filling devices such as pessaries or spheres can be worn in the vagina to elevate the uterine prolapse. Intravaginal estrogen therapy may be prescribed for the postmenopausal woman to prevent atrophy and weakening of vaginal walls. Women with bladder symptoms may benefit from bladder training and attention to complete emptying. Management of a rectocele focuses on promoting bowel elimination. The health care provider usually prescribes a high-fiber diet, stool softeners, and laxatives.

Surgical Management

Surgery may be recommended for severe symptoms. Address the fears and concerns of the patient and her family. The least invasive procedure is usually used.

Transvaginal repair for pelvic organ prolapse (POP) using surgical vaginal mesh or tape is a commonly performed minimally invasive technique. It is particularly useful for women who are very obese. Depending on the procedure that is planned, the patient has either local or general anesthesia. The surgeon creates a sling with the mesh or tape, and the woman is discharged the same day. Procedures done under local anesthesia can be done in the surgeon's office. Over the past several years, patient report of several rare complications associated with the use of transvaginal mesh has required the U.S. Food and Drug Administration to recall at least one company's product. These complications include vaginal erosion and severe infection (Mirsaidi, 2009).

Patients who choose to have the procedure may return to usual activities, including driving, 2 weeks after surgery. Teach them to avoid sexual intercourse for at least 6 weeks or as the surgeon recommends.

Alternatives to minimally invasive surgery are open surgical techniques. An **anterior colporrhaphy** (anterior repair)

FIG. 74-2 Types of uterine prolapse.

FIG. 74-3 In cystocele, the urinary bladder is displaced downward, causing bulging of the anterior vaginal wall. In rectocele, the rectum is displaced, causing bulging of the posterior vaginal wall.

! NURSING SAFETY PRIORITY

Action Alert

To help patients decide if she should decide on any surgical procedure using mesh or tape, be sure that the patient has received informed consent prior to surgery. Teach the patient about these possible adverse events, the signs and symptoms of infection, and when she should contact her surgeon. If possible, provide the patient with the manufacturer's labeling and written information.

tightens the pelvic muscles for better *bladder* support. A vaginal surgical approach is used and may be done as a laparoscopic-assisted procedure. Nursing care for a woman undergoing an anterior repair is similar to that for a woman undergoing a vaginal hysterectomy.

After surgery, instruct the patient to limit her activities. *Teach her to avoid lifting anything heavier than 5 pounds, strenuous exercises, and sexual intercourse for 6 weeks.* For discomfort, tell her to use heat either as a moist heating pad or warm compresses applied to the abdomen. A hot bath may also be helpful. Sutures do not need to be removed because some are absorbable and others will fall out as healing occurs. Tell the woman to notify her health care provider if she has signs of infection, such as fever, persistent pain, or purulent, foul-smelling discharge. Encourage her to keep her follow-up appointment after surgery.

Posterior colporrhaphy (posterior repair) reduces *rectal* bulging. If both a cystocele and a rectocele are present, an *anterior and posterior colporrhaphy (A&P repair)* is performed.

The nursing care after a posterior repair is similar to that after any rectal surgery. After surgery, a low-residue (low-fiber) diet is usually prescribed to decrease bowel movements and allow time for the incision to heal. Instruct the patient to avoid straining when she does have a bowel movement so that she does not put pressure on the suture line. Bowel movements are often painful, and she may need pain medication before having a stool. Provide sitz baths or delegate this activity to unlicensed nursing personnel to relieve the

woman's discomfort. Health teaching for the patient undergoing a posterior repair is similar to that for the patient undergoing an anterior repair.

Vaginal hysterectomy may accompany any uterine prolapse repair surgery unless the woman wants children or more children. This procedure is described on p. 1619.

BENIGN NEOPLASMS

OVARIAN CYST

Functional ovarian cysts can occur in a woman of any age but are rare after menopause. Other cysts and tumors of the ovaries are not related to the menstrual cycle but arise from ovarian tissue. Primary assessment involves pelvic examination and transvaginal ultrasound. Further testing with computerized tomography (CT), magnetic resonance imaging (MRI), or laparoscopic biopsy to rule out cancer may be indicated. Some ovarian cysts disappear over time, and others cause discomfort for a prolonged period. Laparoscopic surgery to remove the cyst or ovary may be needed.

UTERINE LEIOMYOMA

Pathophysiology

Leiomyomas, also called **fibroids** or **myomas**, are benign, slow-growing solid tumors of the uterine myometrium (muscle layer). They are classified according to their position in the layers of the uterus. The most common types are intramural, submucosal, and subserosal (Fig. 74-4).

Intramural leiomyomas are contained in the uterine wall within the myometrium. *Submucosal* leiomyomas protrude into the cavity of the uterus and can cause bleeding and disrupt pregnancy. *Subserosal* leiomyomas protrude through the outer surface of the uterine wall and may extend to the broad ligament, pressing other organs.

Although most fibroids develop within the uterine wall, a few may appear in the cervix. Pedunculated leiomyomas are attached by a pedicle (stalk) to the outside of the uterus and

FIG. 74-4 Classification of uterine leiomyomas.

occasionally break off and attach to other tissues (parasitic fibroids).

Although the cause is not known, leiomyomas develop from excessive local growth of smooth muscle cells. This may be a genetic error causing a lack of ability to halt growth. The growth of leiomyomas may be related to stimulation by estrogen, progesterone, and growth hormone. This explains why fibroids sometimes enlarge during pregnancy and diminish in size after menopause.

The incidence of leiomyomas increases as women get older. Women who have never been pregnant also are at a high risk. Many women have asymptomatic fibroids, whereas others have severe symptoms.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Women with fibroids do not usually have pain, although acute pain may occur with twisting of the fibroid on its stalk. *The patient often seeks medical attention because of heavy vaginal bleeding.* Ask about how many tampons or menstrual pads she uses a day. The woman may report a feeling of pelvic pressure, constipation, or urinary frequency or retention. These symptoms result when an enlarged fibroid presses on other organs. The patient may notice that her abdomen has increased in size. Assess the woman's abdomen for distention or enlargement. Ask if she has dyspareunia (painful intercourse) and infertility (inability to become pregnant).

Abdominal, vaginal, and rectal examinations usually reveal the presence of a uterine enlargement. Further diagnostic procedures are needed to differentiate benign tumors from cancerous ones.

Symptoms such as dyspareunia may significantly lower the patient's quality of life. A woman who is symptomatic may fear that she has cancer. She may be anxious about abnormal bleeding or her failure to conceive. She may also be concerned if surgery is recommended if she wants to have children or more children. Assess the woman's feelings and concerns about her symptoms and fears of the unknown. If hysterectomy is recommended, explore the significance of the loss of the uterus for the woman and her partner. Discuss sexuality issues with the patient based on your assessment.

A complete blood count may identify iron deficiency anemia (related to bleeding). A pregnancy test is done to determine whether pregnancy is the cause of the uterine enlargement. An endometrial biopsy may be performed to evaluate for endometrial cancer.

Transvaginal ultrasound alone or with saline infusion (saline sonogram) provides a good picture of a submucosal fibroid that may protrude into the uterine cavity. The clinician may then choose to directly view a tumor and perform a biopsy of it, using *laparoscopy* (for tumors on the outside of the uterus) or *hysteroscopy* (for tumors accessible inside the uterus). *Magnetic resonance imaging (MRI)* can differentiate between benign and malignant lesions.

INTERVENTIONS

Asymptomatic fibroids do not need treatment. The choice of management depends on the size and location of the tumor and the woman's desire for future pregnancy. Women who still desire pregnancy can take drug therapy or have magnetic

resonance-guided focused ultrasound surgery or laparoscopic myomectomy to remove the tumor. Uterine artery embolization and hysterectomy are choices for women who no longer desire pregnancy.

Nonsurgical Management

If the woman is menopausal, the fibroids usually shrink and surgery may not be necessary. *Teach the patient who is receiving hormone replacement therapy for menopausal symptoms that the fibroids may continue to grow because of estrogen stimulation.*

If the woman has few symptoms or desires childbearing, the health care provider may recommend observation and examination every 4 to 6 months. As with dysfunctional uterine bleeding, mild leiomyoma symptoms can be managed with oral contraception. *Gonadotropin-releasing hormone (GnRH) agonists* such as goserelin (Zoladex) and leuprolide (Lupron Depot) induce artificial menopause but are less commonly used in the past few years due to side and adverse effects. These drugs decrease hormone exposure and may give the tumor time to shrink temporarily. This may also be done before surgery.

Magnetic resonance-guided focused ultrasound is a noninvasive, painless technique for women with few smaller fibroids who wish to preserve their fertility. The woman lies prone on an MRI scanner, which provides a three-dimensional image of the pelvis. The radiologic clinician then guides a focused pulse of ultrasound to heat the tumor to destroy it.

An alternative to surgery for the woman who does not desire pregnancy is **uterine artery embolization** (also called *uterine fibroid embolization [UFE]*) under moderate sedation. The interventional radiologist uses a percutaneous catheter inserted through the femoral artery to inject polyvinyl alcohol pellets into the uterine artery. The resulting blockage starves the tumor of circulation, allowing it (or them) to shrink. The patient stays overnight in the hospital.

! NURSING SAFETY PRIORITY

Action Alert

After uterine artery embolization, the woman may have severe cramping caused by decreased blood flow to the uterus. Cramping continues for 2 to 4 days. Assess her pain level, and provide analgesics as needed. If a vascular closure device is used at the arterial insertion site (most commonly), raise the head of the bed. Help the patient ambulate in about 2 hours after the procedure. If a closure device was not used, keep her on bedrest with the legs immobilized for 4 hours before ambulating to prevent bleeding.

Before discharge, tell the patient to observe for post-embolization syndrome, a flu-like illness that some women develop. Teach her to resume usual activities slowly. Most patients can return to work or daily routine within a week. She should avoid strenuous activity until the physician recommends it.

Surgical Management

When possible, minimally invasive surgical (MIS) techniques are performed, such as a myomectomy. If not, a hysterectomy is the procedure of choice.

Uterus-Sparing Surgeries. If the woman desires children, the surgeon may perform a laparoscopic or hysteroscopic

myomectomy (the removal of leiomyomas from the uterus). During this procedure, a laser may be used to remove the tumors. This minimally invasive procedure is usually performed in the early phase of the menstrual cycle to minimize blood loss and to avoid the possibility of interrupting an unsuspected pregnancy. A small percentage of leiomyomas recur after surgery. Scarring makes the uterus more likely to rupture during labor, so future deliveries will be planned cesarean deliveries. Nursing care is similar to that for a woman undergoing a hysterectomy (see below).

In selected cases (e.g., submucous fibroids, menorrhagia), a *transcervical endometrial resection (TCER)* is performed via hysteroscopy. A hysteroscope (endoscope) is inserted into the uterus, and the endometrium is destroyed using diathermy (heat) or radioablation.

! NURSING SAFETY PRIORITY

Critical Rescue

Monitor for rare but potential complications of hysteroscopic surgery, which include:

- Fluid overload (fluid used to distend the uterine cavity can be absorbed)
- Embolism
- Hemorrhage
- Perforation of the uterus, bowel, or bladder and ureter injury
- Persistent increased menstrual bleeding
- Incomplete suppression of menstruation

Monitor for any indications of these problems, and report signs and symptoms, such as severe pain and heavy bleeding, to the surgeon immediately. Scarring may cause a small risk for complications in future pregnancies.

Hysterectomy. Leiomyomas are the most common reason for hysterectomies. A uterus that has smaller fibroids may be removed via a *total vaginal hysterectomy (TVH)*. The surgeon may perform a laparoscopic-assisted vaginal hysterectomy (LAVH) or use a robotic-assisted operative system (Everett & Crawford, 2010). The surgeon removes the uterus and cervix, sometimes in pieces, through the vagina without an external surgical incision.

A *total abdominal hysterectomy (TAH)* is usually performed for leiomyomas larger than the size of a 16-week pregnancy. The uterus and cervix are removed by laparoscopic-assisted minimally invasive surgery (MIS), which requires one or more very small umbilical incisions through a horizontal bikini incision (traditional open procedure). Some surgeons use robotic technology to assist in performing a TAH (Matthews et al., 2010). Robotic surgery is especially helpful when performing hysterectomies on patients who are extremely obese (Stone et al., 2010). In both vaginal and abdominal hysterectomies, the surgeon removes the uterus from the five supporting ligaments, which are then attached to the vaginal cuff so that normal depth of the vagina is maintained (Table 74-2).

Preoperative teaching by the health care team begins in the surgeon's office. Explain procedures that routinely take place before surgery, including laboratory tests and expected drugs such as a prophylactic antibiotic. Depending on the type of surgical technique planned, teach about the need for turning, coughing, and deep-breathing exercises; incentive spirometry; early ambulation; and pain relief (see Chapter 16 for a discussion of general patient care before surgery).

TABLE 74-2 COMMON GYNECOLOGIC SURGERIES

Total Hysterectomy

All the uterus, including the cervix, is removed. The procedure may be vaginal or abdominal, with laparoscopic or robotic assistance.

Bilateral Salpingo-Oophorectomy (BSO)

Fallopian tubes and ovaries are removed.

Panhysterectomy

Total abdominal hysterectomy and BSO: The uterus, ovaries, and fallopian tubes are removed.

Radical Hysterectomy

The uterus, cervix, adjacent lymph nodes, the upper third of the vagina, and the surrounding tissues (parametrium) are removed.

Psychological assessment is essential. Assess the significance of the surgery for the woman and her partner. If it involves loss of the uterus, she may feel a great loss if she wishes to retain her childbearing ability. Many women relate their uterus to self-image and femininity or believe that their sexual function is related to their uterus. Although surgical menopause by hysterectomy can create loss of libido and vaginal changes, teach the patient that vaginal estrogen cream and gentle dilation can help correct that. Reassure her regarding any misperceptions about the effects of hysterectomy, such as association with masculinization and weight gain. Assess the patient's support system. She may fear rejection by her sexual partner. Include the partner in all teaching sessions, unless this practice is not culturally acceptable.

Patients who have *uterus-sparing surgeries* usually go home the same day of surgery. They often experience less postoperative pain and fewer complications when compared with patients who have their uterus and cervix removed. Teach patients that they usually return to usual daily activities in 2 weeks, but sexual intercourse should be avoided for at least 6 weeks.

Postoperative care of the woman who has undergone a TAH is similar to that of any patient who has had laparoscopic or traditional open abdominal surgery (see Chapter 18). Assess (Chart 74-5):

- Vaginal bleeding (there should be less than one saturated perineal pad in 4 hours)
- Abdominal bleeding at the incision site(s) (a small amount is normal)
- Intactness of the incision(s)
- Urine output per urinary catheter for 24 hours or less (for open surgery)
- Pain

Specific postoperative interventions for a *vaginal hysterectomy* include:

- Assessment of vaginal bleeding (there should be less than one saturated pad in 4 hours)
- Urinary catheter care
- Perineal care

Community-Based Care

The patient with uterine leiomyomas is managed on an ambulatory care basis unless surgery is performed. After discharge, she usually returns to her home.

CHART 74-5 FOCUSED ASSESSMENT

Postoperative Nursing Care of the Patient After Total Abdominal Hysterectomy

Assess cardiovascular, respiratory, renal, and gastrointestinal status, including:

- Vital signs
- Heart, lung, and bowel sounds
- Urine output
- Temperature and color of the skin
- Red blood cell, hemoglobin, and hematocrit levels
- Activity tolerance
- Dressing and drains for color and amount of drainage
- Pads for vaginal bleeding and clots
- Fluid intake (IVs until peristalsis returns and patient is tolerating oral intake)

Teach the patient to use these interventions to prevent postoperative complications:

- Cough and deep-breathing exercises
- Incentive spirometry
- Sequential compression devices
- Ambulation
- Avoidance of heavy lifting or strenuous activity
- Adequate hydration

Assess the home care teaching needs of the patient related to the illness and surgery, including:

- Physiologic effects of the surgery
- Signs or symptoms to report
- Side or toxic effects of medications
- Activity limitations related to driving and use of stairs
- Follow-up care
- Postoperative restrictions related to sexual activity, use of tampons, and bathing
- Care of wound and/or drains

Assess the patient's coping skills and reaction to the diagnosis and surgical procedure.

**NCLEX EXAMINATION CHALLENGE****Physiological Integrity**

A client returns from surgery after a total vaginal hysterectomy. What is the nurse's priority action immediately after surgery?

- Assess for excessive vaginal bleeding.
- Monitor temperature for infection.
- Assess for deep vein thrombosis.
- Check dressing for intactness.

If the patient had a hysterectomy, teach her to limit stair climbing for several weeks. If she lives alone and is not permitted to drive for 2 to 6 weeks, she will need to arrange for transportation for follow-up surgical visits.

Teach the woman who has undergone an abdominal hysterectomy about the expected physical changes, any activity restrictions, diet, sexual activity, wound care, complications, and the need for follow-up care. Chart 74-6 lists areas to include for health teaching.

Generally, women adjust well to surgery if they have completed childbearing, have interests outside the home, work, have no misconceptions about the effects of hysterectomy, and have support from the family, especially their sexual partner. Psychological reactions can occur months to years after surgery, particularly if sexual functioning and libido are diminished. Women identified as being at high risk for psychological problems may need long-term follow-up care or referral. They may need to be counseled about signs of

CHART 74-6 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Care After a Total Vaginal or Abdominal Hysterectomy**Expected Physical Changes**

- You will no longer have a period, although you may have some vaginal discharge for a few days after you go home.
- It will not be possible for you to become pregnant, and birth control methods are no longer needed.
- If your ovaries were removed, you may have some menopause symptoms such as hot flashes, night sweats, and vaginal dryness.
- It is normal to tire more easily and require more sleep and rest during the first few weeks after surgery.

Activity

- Limit stair climbing to fewer than five times per day.
- Do not lift anything heavier than 5 to 10 lbs.
- Gradually increase walking as exercise, but stop before you become fatigued.
- Avoid the sitting position for any extended period. When you sit, do not cross your legs at the knees.
- Avoid jogging, aerobic exercise, participating in sports, and any strenuous activity for 2 to 6 weeks, depending on what type of surgical procedure was performed.
- Do not drive until your surgeon has told you it is alright.

Sexual Activity

- Do not engage in sexual intercourse for 4 to 6 weeks, or as prescribed by your surgeon.
- If you had a vaginal "repair" as part of your surgery, the first time you have intercourse you may have some tenderness or pain because the vaginal walls are tighter. Careful intercourse and the use of water-based lubricants can help reduce this discomfort. This discomfort usually goes away with time and stretching of the vagina.

Complications

- Take your temperature twice each day for the first 3 days after surgery.
- Check your incision, if you have any, daily for signs of infection (increasing redness, open areas, drainage that is thick or foul-smelling, incision pain).

Report Any of the Following to Your Surgeon

- Increased vaginal drainage or change in drainage (bloodier, thicker, foul-smelling)
- Temperature over 100° F
- Pain, tenderness, redness, or swelling in your calves
- Pain or burning on urination

depression. Intermittent sadness is normal, but continued feelings of low self-esteem or loss of interest or pleasure in usual activities and pastimes is not normal and should be evaluated. Provide written materials, and focus on the positive aspects of the woman's life to help decrease adverse psychological reactions.

BARTHOLIN CYST**Pathophysiology**

Bartholin cyst is a common disorder of the vulva. It results from obstruction of the duct of the Bartholin gland. The secretory function of the gland continues, and the fluid fills the obstructed duct. The main causes of the obstruction are

infection, thickened mucus near the ductal opening, or trauma, such as lacerations.

PATIENT-CENTERED COLLABORATIVE CARE

The patient may be asymptomatic if the cyst is small. Ask if she has dyspareunia (painful intercourse) or inadequate genital lubrication. Assess for swelling in the perineal area. A large cyst usually causes constant local pain and may cause difficulty walking or sitting. Physical examination of the vulva reveals a swelling immediately beneath the skin in the posterior portion of the vulva. The cyst may appear brown or bloody, depending on its contents. Usually it is present on only one side and ranges from $\frac{3}{8}$ to 4 inches (1 to 10 cm) in size.

If the cyst is draining, a fluid sample is sent to the laboratory for culture (for gonorrhea and aerobic and anaerobic organisms) and sensitivity testing. If the woman is older than 40 years, a biopsy of the cyst is done to identify possible cancer.

If the woman is asymptomatic, no intervention is needed. An abscess usually ruptures spontaneously within 72 hours of forming. Teach the woman with an abscess to take over-the-counter or prescribed analgesics and apply moist heat (sitz baths or hot wet packs) to the vulva. Cultures most often reveal *Escherichia coli* or *Staphylococcus aureus*, for which antibiotics are prescribed.

Simple incision and drainage (I&D) may provide temporary relief. However, cysts tend to recur when the opening of the duct re-obstructs. Usually the surgeon establishes a permanent opening for drainage. **Marsupialization** (formation of a pouch that is a new duct opening) is performed using local, regional, or general anesthesia. Discomfort after surgery may be relieved with analgesics and sitz baths. Prophylactic antibiotics may be prescribed.

The Bartholin glands may be totally removed in older women when cancer is suspected or if infections with abscess formation recur. Care after surgery includes:

- Application of ice packs or sitz baths several times a day for comfort and promotion of healing
- Analgesics for pain
- Prophylactic antibiotics
- Assessment of the incision for signs of healing or infection

CERVICAL POLYP

Cervical polyps are *pedunculated* (on stalks) tumors that arise from the mucosa and extend through the opening of the cervical os. They result from a hyperplasia (overgrowth) of the endocervical epithelium in response to hormonal stimulation. Polyps may also be due to inflammation or to localized vascular congestion of the cervical blood vessels. They are the most common benign growth of the cervix and occur most often in women older than 40 years who have had several children.

A woman may be asymptomatic, have premenstrual or postmenstrual bleeding, or have bleeding after intercourse. A speculum examination may reveal a small single polyp or multiple polyps. They are bright red, are soft and fragile, and may bleed when touched.

Polyp removal is a simple office procedure. The base of the polyp is grasped with a clamp, and the polyp is twisted off and sent to the pathology laboratory for evaluation. Cautery

usually stops any bleeding at the site of removal. The woman does not feel any pain during the procedure. Instruct her to avoid tampon use, douches, and sexual intercourse for a week or until healing has taken place.

GYNECOLOGIC CANCERS

ENDOMETRIAL (UTERINE) CANCER

Pathophysiology

Endometrial cancer (cancer of the inner uterine lining) is the most common gynecologic malignancy in the United States. This chapter includes two other common gynecologic cancers, but the disease can affect any organ in the reproductive tract.

Endometrial cancer grows slowly in most cases, and early symptoms of vaginal bleeding generally lead to prompt evaluation and treatment. As a result, this type of cancer has a good prognosis. *Adenocarcinoma* is the most common type, accounting for 80% of all cases. The tumor arises from the glandular part of the endometrium and usually follows endometrial hyperplasia (overgrowth).

The initial growth of the cancer is within the uterine cavity, followed by extension into the myometrium and the cervix. Stage I endometrial cancer is confined to the endometrium. Stage II cancer also involves the cervix, and stage III reaches the vagina or lymph nodes. Stage IV endometrial cancer has spread beyond the pelvis.

Metastasis outside the uterus occurs in these ways:

- Through lymphatic spread to the ovaries and parametrial, pelvic, inguinal, and para-aortic lymph nodes
- By blood, to the lungs, liver, or bone
- By transtubal or intra-abdominal spread to the peritoneal cavity

Etiology and Genetic Risk

Endometrial cancer is strongly associated with conditions causing prolonged exposure to estrogen without the protective effects of progesterone. Risk factors for endometrial cancer are listed in [Table 74-3](#). Although most cases of endometrial cancer do not have a genetic predisposition, it is more common in families who have gene mutations for hereditary nonpolyposis colon cancer (HNPCC) (Nussbaum et al., 2007).

Incidence and Prevalence

About 44,000 new cases of endometrial cancer occur annually in the United States. White women get the disease more often than African-American women, but African-American women die more often from the disease (American Cancer Society [ACS], 2010). Factors accounting for the differences in these death rates may include access to care and patient education opportunities.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Physical Assessment/Clinical Manifestations

The main symptom of endometrial cancer is postmenopausal bleeding. Ask the patient how many tampons or menstrual pads she uses each day. Some women also have a watery, bloody vaginal discharge, low back or abdominal pain, and low pelvic

TABLE 74-3 RISK FACTORS FOR ENDOMETRIAL (UTERINE) CANCER AND CERVICAL CANCER

ENDOMETRIAL (UTERINE) CANCER	CERVICAL CANCER
• Women in reproductive years • Family history of endometrial cancer or HNPCC • Diabetes mellitus • Hypertension • Obesity • Uterine polyps • Late menopause • Nulliparity (no childbirths) • Smoking • Tamoxifen (Nolvadex) given for breast cancer	• Girls and young women • Infection with HPV • Multiparity (multiple births) • Smoking • Younger than 18 years at first intercourse • Multiple sex partners • African American • Oral contraceptive use • History of STDs • Obesity or poor diet • Family history of cervical cancer • HIV/AIDS • Lower socioeconomic status • Sexual partner had a previous partner who developed cervical cancer • Intrauterine exposure to DES

AIDS, Acquired immune deficiency syndrome; DES, diethylstilbestrol; HIV, human immune deficiency virus; HNPCC, hereditary nonpolyposis colon cancer; HPV, human papilloma virus; STDs, sexually transmitted diseases.

pain (caused by pressure of the enlarged uterus). Ask the patient to describe the exact location and intensity of her discomfort. A pelvic examination may reveal the presence of a palpable uterine mass or uterine polyp. The uterus is enlarged if the cancer is advanced.

Laboratory Assessment

Several laboratory tests are used to determine the overall condition of the woman with possible or confirmed endometrial cancer. For example, the complete blood count typically shows anemia because the patient has heavy bleeding. Serum tumor markers to assess for metastasis include CA-125 (cancer antigen-125) and alpha-fetoprotein (AFP), both of which may be elevated when ovarian cancer is present (Pagana & Pagana, 2010). A human chorionic gonadotropin (hCG) level may be taken to rule out pregnancy before treatment for cancer begins. Genetic testing may be done for the mutation causing HNPCC, if there is a family history of this disease.

Other Diagnostic Assessment

Transvaginal ultrasound and *endometrial biopsy* are the gold standard tests to determine the presence of endometrial thickening and cancer. Saline may be infused during the ultrasound to improve the image of the uterine cavity. The clinician then collects an endometrial biopsy from inside the uterus via a thin, flexible suction curette through the cervix (Pagana & Pagana, 2010).

Other diagnostic tests to determine the patient's overall health status and the presence of metastasis (cancer spread) include:

- Chest x-ray
- Intravenous pyelography (IVP), or excretory urography, to assess renal function and to assess for renal metastasis
- Abdominal ultrasound

- Computed tomography (CT) of the pelvis
- Magnetic resonance imaging (MRI) of the abdomen and pelvis
- Liver and bone scans to assess for distant metastasis

Some women also have a hysteroscopic examination of the uterus and proctosigmoidoscopy depending on the stage of their cancer.

Psychosocial Assessment

Before a diagnosis is made, the woman may deny that the symptoms are related to cancer. During the diagnostic phase, the woman may express fears and concerns about having the disease. After the diagnosis is confirmed, she may express disbelief, anger, depression, anxiety, or withdrawal behaviors. Assess these emotional reactions, and encourage the patient to discuss them. Ask her about how she copes with other stressful events, and assess her support systems.

ANALYSIS

The priority problems for patients with endometrial cancer are:

1. Potential for disease metastasis
2. Ineffective Coping related to the diagnosis of cancer and fear of dying

PLANNING AND IMPLEMENTATION

Reducing the Risk for Metastasis

Planning: Expect Outcomes. The patient is expected to be free of metastatic disease if she has been diagnosed without obvious metastasis. For patients whose cancer has already spread, the expected outcomes are to have the highest quality life for as long as possible. In some cases, palliation and end-of-life care are desired.

Interventions. Surgical removal and cancer staging of the tumor with adjacent lymph nodes are the most important interventions for endometrial cancer. Cancer staging is often done using minimally invasive techniques, such as laparoscopic or robotic-assisted procedures.

Surgical Management. For stage I disease, the gynecology oncologist usually removes the uterus, fallopian tubes, and ovaries (**total hysterectomy** and **bilateral salpingectomy/oophorectomy [BSO]**), as well as peritoneum fluid or washings for cytologic examination. Laparoscopic surgery has fewer complications, shorter hospital stay, and less cost. A radical hysterectomy with bilateral pelvic lymph node dissection and removal of the upper third of the vagina is performed for stage II cancer. Nursing care for a radical hysterectomy is the same as that for a simple hysterectomy except that the woman's hospitalization is usually longer and her convalescence may be extended. Radical surgery and node dissection can also be done as a minimally invasive procedure using laparoscopic or robotic-assisted technology.

Nonsurgical Management. Nonsurgical interventions (radiation therapy and chemotherapy) are used postoperatively and depend on the surgical staging.

Radiation Therapy. The oncologist prescribes radiation therapy to be delivered by external beam and/or brachytherapy for stage II and stage III cancers. Women with stage II disease may use brachytherapy (internal) radiation to prevent recurrence of vaginal cancer and improve survival.

The purpose of *brachytherapy* is to prevent disease recurrence. This treatment no longer requires a hospital stay and

CHART 74-7 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Health Teaching for the Patient Having Brachytherapy for Gynecologic Cancer

Teach the patient to report any of these signs and symptoms to the health care provider immediately:

- Heavy vaginal bleeding
- Urethral burning for more than 24 hours
- Blood in the urine
- Extreme fatigue
- Severe diarrhea
- Fever over 100° F (38° C)
- Abdominal pain

Teach the patient that she is not radioactive between treatments and there are no restrictions on her interactions with others.

is done on an ambulatory care basis. The radiologist places an applicator within the woman's uterus through the vagina. After the correct position of the applicator is confirmed by x-ray, the radioactive isotope is placed in the applicator and remains for several minutes. This procedure may be repeated between 2 and 5 times once or twice a week. Some patients also have external beam radiation while having brachytherapy treatment sessions. There are no restrictions for the woman to stay away from her family or the public between treatments.

While the radioactive implant is in place, radiation is emitted that can affect other people. The amount of time needed for the therapy depends on the amount of radiation emitted from the source. The radiologist calculates the time needed for a specific dose of radiation.

Inform the patient that she is restricted to bedrest during the treatment session. Excessive movement in bed is restricted to prevent dislodgment of the radioactive source.

Chart 74-7 lists the best practices for radiation precautions while caring for the patient receiving brachytherapy. Teach patients about when to call the health care provider after each treatment session.

External *beam radiation therapy (EBRT)* may be used to treat any stage of endometrial cancer in combination with surgery, brachytherapy, and/or chemotherapy. Depending on the extent of the tumor, the treatment is given on an ambulatory care basis for 4 to 6 weeks. Tissue around the tumor and pelvic wall nodes also are treated. *Teach the patient to monitor for signs of skin breakdown, especially in the perineal area; to avoid sunbathing; and to avoid washing the markings outlining the treatment site.*

Drug Therapy. Chemotherapy is used as palliative treatment in advanced and recurrent disease when it has spread to distant parts of the body, but it is not always effective. Although the combination can vary, three of the most common agents used for endometrial cancer are doxorubicin (Adriamycin), cisplatin (Platinol), and paclitaxel (Taxol). Chapter 24 describes chemotherapy and general nursing care during treatment.

Every woman experiences cancer differently. Many complementary therapies have evidence of benefit in decreasing the side effects of drug therapy and boosting the immune system. Help her make informed, evidence-based decisions.

Encourage her to check with her oncologist and/or pharmacist because some alternative therapies can be harmful or interfere with cancer treatment. Current evidence-based information is available about mind-body therapies, healing touch, herbs, vitamins, nutrition, and biologic therapies at the American Cancer Society website (www.cancer.org).

Helping the Patient Develop Coping Strategies

Planning: Expected Outcomes. The patient is expected to develop coping strategies that will help her deal with the diagnosis and collaborative care for endometrial cancer.

Interventions. Women need to discuss their concerns about the presence of cancer and the potential for recurrence. Provide emotional support, and create an atmosphere that encourages them to ask questions or express their fears and concerns. Include family members or significant others in discussions when possible.

Reactions to radiation therapy vary. Some women feel radioactive or “unclean” after treatments and may exhibit withdrawal behaviors. Reassure them by correcting any misconceptions. Patients who have chemotherapy may be upset if **alopecia** (hair loss) occurs. Warn them of this possibility before treatment starts. Wigs, scarves, or turbans can be worn until the hair grows back. Many women select these replacements before they lose their hair. Others shave their heads and begin wearing them immediately as the treatment begins. Tell women about these options so that they can make the best decision for them.

Often patients experience emotional crises because of the physical effects of cancer treatments. Radical hysterectomy may be seen as mutilating. Both radiation and chemotherapy have side effects that change physical appearance and body image. Women often may have a grief reaction to these changes. The feelings of loss depend on the visibility of the loss and the loss of function. Help the patient adapt to the body changes. One way to do this is to encourage self-management as soon as her physical condition is stable. Use a calm and accepting attitude.

Death can occur with or without treatment. The patient and family want the woman to pass the 5-year survival mark without a recurrence of disease. If there is a recurrence, they may be hostile and have manifestations of a grief reaction. Encourage patients and their families to discuss their feelings. Refer to support services such as certified hospital chaplain or other spiritual leader, social worker, or counselor. Response to loss and grieving is discussed in Chapter 9.

Community-Based Care

Home Care Management

The woman with endometrial cancer is managed at home unless surgery is indicated. After surgery, she is usually discharged to her home. Home care after surgery for endometrial cancer is the same as that after a hysterectomy. (See discussion of Hysterectomy on p. 1619 in the Uterine Leiomyoma section.) Patients who are receiving chemotherapy or radiation therapy are treated on an ambulatory care basis. Most women are surprised by the fatigue caused by radiation and chemotherapy. Help the patient and her family plan daily activities around trips to the clinic or the health care provider's office. If the tumor recurs and cure is not likely, the woman and her family need to think about hospice care and whether she can be cared for in the home.

Teaching for Self-Management

Teach the patient to report vaginal or rectal bleeding, foul-smelling discharge, abdominal pain or distention, and hematuria to the health care provider. These symptoms may be the result of the disease or its treatment.

The high dose of radiation causes sterility, and vaginal shrinkage can occur. Vaginal dilators can be used with water-soluble lubricants for 10 minutes each day until sexual activity resumes (in 10 days to 6 weeks). Reassure the woman that she is not radioactive and that her partner will not “catch” cancer by engaging in sexual intercourse.

Review all prescribed drugs, including the dosage and schedule, effects, and side effects. Emphasize the importance of keeping appointments for follow-up care.

Health Care Resources

In the United States, local American Cancer Society chapters provide written materials about endometrial cancer and information about local support groups. Each province in Canada also has a division of the Canadian Cancer Society (www.cancer.ca). If the patient is in the terminal stages of cancer, hospice care may be appropriate (see [Chapter 9](#)). If nursing care is needed at home, the hospital nurse or case manager makes referrals to a home health care agency. A referral to a social services agency may be needed if the patient cannot meet the financial demands of treatment and long-term follow-up.

DECISION-MAKING CHALLENGE

Patient-Centered Care; Evidence-Based Practice; Informatics; Teamwork and Collaboration

A 58-year-old woman is diagnosed with ovarian cancer today. She begins to cry and tells you that she “had a feeling all along” that she had the disease. No one in her family has had ovarian cancer, but she has two friends who recently died of the disease. She is scheduled for an exploratory laparotomy and tumor debulking in 3 days. Her oncologist told her that after she recovers from surgery, she will have brachytherapy and external beam radiation therapy (EBRT).

1. What preoperative teaching will you provide for this patient and why?
2. What will you tell her about restrictions associated with brachytherapy and EBRT?
3. Where would you search for evidence about her expected quality of life and prognosis?
4. What members may need to be involved in her care?

CERVICAL CANCER

Pathophysiology

The uterine cervix is covered with squamous cells on the outer cervix and columnar (glandular) cells that line the endocervical canal. Papanicolaou (Pap) tests sample cells from both areas as a screening test for cervical cancer. The squamo-columnar junction is the *transformation zone* where most cell abnormalities occur. The adolescent has more columnar cells exposed on the outer cervix, which may be one reason she is more vulnerable to sexually transmitted diseases (STDs) and human immune deficiency virus (HIV). In contrast, in the menopausal woman, the squamo-columnar junction may be higher up in the endocervical canal, making it difficult to sample for a Pap test.

Premalignant changes are described on a continuum from atypia (suspicious) to *cervical intraepithelial neoplasia (CIN 1)* to *carcinoma in situ (CIS)*, which is the most advanced premalignant change. It generally takes years for the cervical cells to transform from normal to premalignant to invasive cancer. Many CIN 2 lesions progress to high-grade dysplasia. CIN 3 lesions can progress to squamous cell carcinoma or adenocarcinoma in situ (AIS).

Most cervical cancers arise from the squamous cells on the outside of the cervix. The other cancers arise from the mucus-secreting glandular cells (adenocarcinoma) in the endocervical canal. The disease spreads by direct extension to the vaginal mucosa, lower uterine segment, parametrium, pelvic wall, bladder, and bowel. Metastasis is usually confined to the pelvis, but distant spread can occur through lymphatic spread and the circulation to the liver, lungs, or bones.

Etiology

Human papilloma virus (HPV) is the most common STD in the United States. Almost all women will have HPV sometime in their life, but not all types lead to cancer. Most cases of cervical cancer are caused by certain types of HPV. Women at the highest risk are those who have a long-standing high-risk HPV strain ([Wells, 2008](#)). The high-risk HPV types, especially strains 16 and 18, impair the tumor-suppressor gene and cause most of the cervical cancers. The unrestricted tissue growth can spread, becoming invasive and metastatic. Strains 6 and 11 are associated with genital warts. Risk factors for cervical cancer are listed in [Table 74-3](#).

Incidence/Prevalence

Invasive cancer of the cervix is the third most common cancer of the female genital system, after ovarian and uterine cancer. Although much less common than breast cancer, cervical cancer has a lower 5-year survival rate (ACS, 2010).

The peak incidence occurs in patients in their mid-20s. It usually resolves spontaneously within a year. Carcinoma in situ (CIS) occurs in women about 30 years old, and invasive cancer occurs most commonly in the late 40s (ACS, 2010).

Health Promotion and Maintenance

Girls and young women should receive one of the two currently used HPV vaccines, Gardasil and Cervarix, ideally before their first sexual contact to receive protection against the highest-risk HPV types that are responsible for most cervical cancers. Gardasil is indicated for ages 9 through 26 years. It is also given for boys and men (ages 9 through 26 years) to prevent genital warts because it protects against the 6 and 11 HPV strains.

Cervarix protects girls and women ages 10 through 25 years against infection for HPV strains 16 and 18 to prevent cervical cancer. It allows for longer-lasting protection when compared with Gardasil.

Teach all young patients about the importance of receiving the vaccine and the need to have the entire series (3 injections over 6 months). Tell them that the most frequent side effects are related to local irritation from the injections (e.g., pain, redness). Other common side effects include nausea, vomiting, dizziness, headache, and diarrhea.

The American Cancer Society (ACS) recommends that women have periodic pelvic examinations and Pap tests to screen for cervical cancer early. Teach women that they should

begin these screening precautions within 3 years after having sexual intercourse or by the age of 21. Some health care providers, however, recommend the first examination and Pap test by age 18. For conventional Pap testing, *annual* screening is recommended by most experts. If the liquid test is used and the woman has no other risk factors (e.g., weakened immune system, HIV), it may be done *every 2 or 3 years* if she has three consecutive normal Pap smears and depending on the health care provider's recommendations. Teach women that if they have a hysterectomy and have no other health risk factors, a Pap test is no longer needed.

Instruct women ages 70 years and older who have had three consecutive normal Pap smears and no abnormal results that they can stop having Pap tests after a discussion with their health care provider. As women age, the usefulness of testing is questionable. The evidence about precise screening frequency remains conflicting (Wells, 2008).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Physical Assessment/Clinical Manifestations

The patient who has preinvasive cancer is often asymptomatic. *The classic symptom of invasive cancer is painless vaginal bleeding.* Ask the patient if she has had or now has bleeding. It may start as spotting between menstrual periods or after sexual intercourse or douching. As the cancer grows, bleeding increases in frequency, duration, and amount and may become continuous.

Ask the woman if she has a watery, blood-tinged vaginal discharge that becomes dark and foul-smelling (occurs as the disease progresses). Leg pain (along the sciatic nerve) or swelling of one leg may be a late symptom or may indicate recurrent disease. Flank pain may be a late symptom of hydronephrosis, indicating advanced cancer pressing on the ureters, backing up the urine into the kidney. Ask the patient if she has had other signs of recurrence or metastasis such as:

- Unexplained weight loss
- **Dysuria** (painful urination)
- Pelvic pain (caused by pressure of the tumor on the bladder or the bowel)
- **Hematuria** (bloody urine)
- Rectal bleeding
- Chest pain
- Coughing

A physical examination may not reveal any abnormalities in early preinvasive cervical cancer. The internal pelvic examination may identify late-stage disease.

Diagnostic Assessment

If Pap results are abnormal, an *HPV-typing DNA test* of the cervical sample can determine the presence of one or more high-risk types. The health care provider may perform a colposcopic examination to view the transformation zone. **Colposcopy** is a procedure in which application of a 3% acetic acid solution is applied to the cervix. The cervix is then examined under magnification with a bright filter light that enhances the visualization of the characteristics of dysplasia or cancer. If abnormal tissue is recognized, multiple biopsies of the cervical tissue are performed.

If atypical glandular cells are suspected, the health care provider may perform an *endocervical curettage* (scraping of the endocervix wall) as well. Inform her that a small amount of bleeding is expected for up to 2 weeks after the biopsies.

INTERVENTIONS

Interventions for the woman with cervical cancer are similar to those for endometrial cancer: surgery, which is possibly followed by radiation and chemotherapy for later-stage disease.

Surgical Management

Early stage I management techniques include local cervical ablation therapies of electrosurgical excision, laser therapy, or cryosurgery. Small tumors that are only microinvasive are managed with excisional conization or hysterectomy. Early-stage *invasive* cancers are managed with radical surgery and radiation. Advanced inoperable cancers are treated with radiation. Factors that influence the choice of localized treatment versus surgical intervention include patient overall health, desire for future childbearing, tumor size, stage, cancer cell type, degree of lymph node involvement, and patient preference.

Early Surgical Procedures. The **loop electrosurgical excision procedure (LEEP)** is short (10 to 30 minutes) and is performed in a physician's office or in an ambulatory care setting with a local anesthetic injected into the cervix. A thin loop-wire electrode that transmits a painless electrical current is used to cut away affected tissue. LEEP is both a diagnostic procedure and a treatment, because it provides a specimen that can be examined by a pathologist to ensure the lesion was completely removed. Little discomfort is associated with this procedure. Spotting after the procedure is common. Teach patients to adhere for 3 weeks to the restrictions listed in Chart 74-8.

Laser therapy is also an office procedure used for early cancers. A laser beam is directed to the abnormal tissues, where energy from the beam is absorbed by the fluid in the tissues, causing them to vaporize. A small amount of bleeding occurs with the procedure, and the woman may have a slight vaginal discharge. Healing occurs in 6 to 12 weeks. A disadvantage of this procedure is that no specimen is available for study.

Cryotherapy involves freezing of the cancer, causing subsequent necrosis. The procedure is often painless, although

CHART 74-8 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Care After Local Cervical Ablation Therapies

- Refrain from sexual intercourse.
- Do not use tampons.
- Do not douche.
- Take showers rather than tub baths.
- Avoid lifting heavy objects.
- Report any heavy vaginal bleeding, foul-smelling drainage, or fever.

The usual time period for these restrictions is 3 weeks. Your health care provider may prescribe a different (longer or shorter) time frame for you.

some women have slight cramping after the procedure. The patient has a heavy watery discharge for several weeks after the procedure. Instruct her to follow the restrictions in [Chart 74-8](#).

In cases of microinvasive cancer, a *conization* can remove the affected tissue while still preserving fertility. This procedure is done when the lesion cannot be visualized by colposcopic examination. A cone-shaped area of cervix is removed surgically and sent to the laboratory to determine the extent of the cancer. Potential complications from this procedure include hemorrhage and uterine perforation. Long-term follow-up care is needed because new cancers can develop.

Hysterectomy. A total hysterectomy may be performed as treatment of microinvasive cancer if the woman does not want children or more children. A laparoscopic vaginal approach is commonly used. A radical hysterectomy and bilateral pelvic lymph node dissection may be as effective as radiation is for treating cancer that has extended beyond the cervix but not to the pelvic wall. Care for patients undergoing hysterectomy is found in the Uterine Leiomyoma section on p. 1619.

Nonsurgical Management

Radiation therapy is reserved for invasive cervical cancer. Brachytherapy and external beam radiation therapy are used in combination, depending on the extent and location of the lesion. The procedure is similar to that described on pp. 1622-1623 for endometrial cancer.

A combination of chemotherapy with cisplatin (Platinol) and radiation may also be used. This treatment modality shows increased survival times but increased toxicity for many patients. Examples of other drugs used alone or in combination include paclitaxel (Taxol), carboplatin, fluorouracil (5-FU), and mitomycin. See [Chapter 24](#) for more information about the general nursing care for the patient on chemotherapy and radiation.

OVARIAN CANCER

Pathophysiology

Most ovarian cancers are epithelial tumors that grow on the surface of the ovaries. These tumors grow rapidly, spread quickly, and are often bilateral. Tumor cells spread by direct extension into nearby organs and through blood and lymph circulation to distant sites. Free-floating cancer cells also spread through the abdomen to seed new sites, usually accompanied by ascites (abdominal fluid).

Ovarian cancer seems to be disordered growth in response to excessive exposure to estrogen. This would explain the protective effects of pregnancies and oral contraceptive use, both of which interrupt the monthly estrogen exposure. [Table 74-4](#) lists known and suspected risk factors for ovarian cancer.

Ovarian cancer is the leading cause of death from female reproductive cancers, but it is not the most common type of cancer. About 22,000 new cases are diagnosed each year, with 14,000 annual deaths (ACS, 2010). The incidence increases in women older than 50 years, and most are diagnosed after menopause. Family history accounts for a small percentage of cases. These women carry *BCRA1* or *BCRA2* genetic mutations. Of these, some choose to have a **bilateral salpingo-oophorectomy (BSO)** (removal of both ovaries and fallopian

TABLE 74-4 RISK FACTORS FOR OVARIAN CANCER

• Older than 40 years • Family history of ovarian or breast cancer or HNPCC • Diabetes mellitus • Nulliparity • Older than 30 years at first pregnancy • Breast cancer	• Colorectal cancer • Infertility • <i>BCRA1</i> or <i>BCRA2</i> gene mutations • Early menarche/late menopause • Endometriosis • Obesity/high-fat diet
---	--

HNPCC, Hereditary nonpolyposis colon cancer.

tubes). This surgery may reduce the risk for ovarian cancer by more than 90% in these patients (Nussbaum et al., 2007).

Survival rates are low because ovarian cancer is often not detected until its late stages. The aging of the population makes it important for nurses to teach women to “*think ovarian*” if they have vague abdominal and GI symptoms.

Health Promotion and Maintenance

Health promotion measures to help prevent ovarian cancer include maintaining a normal weight and eating a well-balanced diet. Women who have had children, used oral contraception for at least 5 years, and breast-fed their children also have less risk for having the disease (Bohnenkamp et al., 2007a).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Most women with ovarian cancer have had mild symptoms for several months but may have thought they were due to normal perimenopausal changes or stress. They may report abdominal pain or swelling or have vague GI disturbances such as dyspepsia (indigestion) and gas. Ask the patient if she has had urinary frequency or incontinence, unexpected weight loss, and/or vaginal bleeding.

Complications of advanced metastatic cancer include:

- Pleural effusion
- Ascites
- Lymphedema
- Intestinal obstruction
- Malnutrition

On pelvic examination, an abdominal mass may not be palpable until it reaches a size of 4 to 6 inches (10 to 15 cm). Any enlarged ovary found after menopause should be evaluated as though it were malignant. A Pap smear is of limited value for detecting ovarian cancer.

A cancer antigen test, *CA-125*, measures the presence of damaged endometrial and uterine tissue in the blood. It may be elevated if ovarian cancer is present, but it can also be elevated in patients with endometriosis, fibroids, pelvic inflammatory disease, pregnancy, and even menses. It is also useful for monitoring a patient's progress during and after treatment. Transvaginal ultrasonography, chest radiography, and computed tomography (CT) are part of a complete workup to evaluate for metastasis. Complete blood work includes a liver profile if there is ascites.

The woman with ovarian cancer has concerns similar to those described for the patient with endometrial cancer.

Because the cancer is often diagnosed in an advanced stage, thoughts of death and dying, menopause, and loss of fertility come as a shock.

INTERVENTIONS

Nursing care of the patient with ovarian cancer is similar to that for endometrial or cervical cancer. The options for treatment depend on the extent of the cancer and usually include surgery first, followed by chemotherapy. Radiation is used for more widespread cancers.

Surgical Management

Diagnosis depends on surgical exploration. Exploratory laparotomy (abdominal surgery) is performed to diagnose, treat, and stage ovarian tumors. A total abdominal hysterectomy, bilateral salpingo-oophorectomy (removal of the ovaries and fallopian tubes), and pelvic and para-aortic lymph node dissection are usually performed. Very large tumors that cannot be removed are debulked (cytoreduction). These procedures can be performed via laparoscopic technique to decrease recovery time, minimize pain, and reduce postoperative complications. Ovarian cancer is staged during surgery.

Nursing care of the patient is similar to that for any patient having abdominal surgery (see Chapter 18). As for any patient after abdominal surgery, assess vital signs and pain and maintain catheters and drains. Teach her the importance of anti-embolism stockings, incentive spirometry, and early ambulation. Infections after ovarian cancer surgery commonly affect the respiratory and urinary tract. Assess vital signs, and monitor the quantity and quality of urine output.

Nonsurgical Management

After cytoreduction and staging of ovarian cancer, chemotherapy is the treatment that is used the most often. For all stages of ovarian cancer, cisplatin (Platinol), carboplatin, and taxanes of all types are the most common postoperative drugs used for treating ovarian cancer. They may be given IV and/or intraperitoneally. Intraperitoneal (IP) therapy is described in Chapter 15. The drugs are usually given every 3 to 4 weeks for six cycles in an inpatient or ambulatory care setting

(Blewitt, 2010). New drugs are being tested that use monoclonal antibodies, hormones, and agents that target cell growth and tumor blood supply.

Community-Based Care

Patients having surgery usually return to their home. Teach them to avoid tampons, douches, and sexual intercourse for at least 6 weeks or as instructed by the health care provider. Remind them to keep their follow-up surgical appointment and talk with the health care provider about resuming usual activities. Refer patients and their families to Gilda's Club (www.gildasclub.org) and the National Ovarian Cancer Coalition (NOCC) (www.ovarian.org) for more information and support groups. In Canada, the National Ovarian Cancer Association (www.ovariancanada.org) is available for the same purpose.

For patients with advanced metastatic disease, collaborate with the case manager, patient, and family for possible referral to hospice. Chapter 9 discusses end-of-life care and hospice in detail. The woman who is faced with the diagnosis of advanced ovarian cancer is usually very anxious about dying. Encourage her to discuss her feelings. Provide realistic assurance, as well as accurate information about treatments. Patients report their most distressing moments in the hospital were when they thought they were not getting adequate information. Encourage them to use their support systems of family members, friends, and clergy, including the hospital chaplain. Grief counseling is very appropriate. A visit from another woman who has survived a similar disease or referral to a support group may decrease fears. Refer the patient who fears passing the *BRCA1* or *BRCA2* gene to her daughter for genetic counseling and testing.

Ovarian cancer has a high recurrence rate. After recurrence, the cancer is treatable but no longer curable. If this occurs, the patient may deny symptoms at first or express feelings of anger and grief. The family is often fearful of the outcome. Provide encouragement and support during this difficult time, and help the patient and her family work through their grief and prepare for death.

NURSING CONCEPT REVIEW

What might you NOTICE if the patient is experiencing impaired sexuality as a result of gynecologic problems?

- Irregular or abnormal vaginal bleeding
- Vaginal discharge
- Report of perineal itching or burning
- Report of painful intercourse
- Abdominal distention and discomfort
- Report of irritability, anxiety, or depression
- Report of decreased libido

What should you INTERPRET and how should you RESPOND to the patient experiencing impaired sexuality as a result of gynecologic problems?

Perform and interpret physical assessment, including:

- Conducting an abdominal assessment
- Conducting a thorough pain assessment

- Checking for bleeding and amount (number of pads or tampons)
- Listening to patient's concerns about her sexuality

Respond by:

- Helping the patient into a sitting position
- Providing pain relief measures, such as heat and analgesia
- Referring the patient to a sexual or intimacy counselor (including the patient's partner if desired)

On what should you REFLECT?

- Think about what else you can do to help provide psychosocial support.
- Prepare for complications, such as hemorrhage, if the patient is bleeding.
- Evaluate pain level after interventions.

GET READY FOR THE NCLEX® EXAMINATION!**KEY POINTS**

Review these Key Points for each NCLEX Examination Client Needs Category.

Safe and Effective Care Environment

- Refer patients with gynecologic problems to appropriate community resources such as the American Cancer Society and the Endometriosis Association.
- Collaborate with the case manager when planning care for patients with gynecologic cancers.

Health Promotion and Maintenance

- Teach women to follow the American Cancer Society's screening guidelines to prevent and early-detect for gynecologic cancers.
- Teach all women to have regular Pap tests based on their risk factors.
- Teach women to practice safe sex to prevent infections of the reproductive organs.
- Teach women about risk factors for gynecologic cancers as described in [Tables 74-3 and 74-4](#).
- Teach women how to prevent toxic shock syndrome (TSS) as listed in [Chart 74-4](#).

Psychosocial Integrity

- Explain all tests, procedures, and treatments, especially if they cause discomfort during or after the procedures.

- Assess the patient's anxiety before any gynecologic surgery.
- Encourage women who are having procedures that may interfere with fertility to express feelings of fear or grief.
- Encourage women with chronic or serious health problems to consider using support groups or counseling.

Physiological Integrity

- Urge any woman who experiences postmenopausal vaginal bleeding to consult with her gynecologic health care provider as soon as possible.
- Assess for clinical manifestations of TSS as listed in [Chart 74-3](#).
- Teach patients about specific restrictions after local cervical ablation therapy (see [Chart 74-8](#)).
- When caring for a patient who has a radioactive implant, use best practices as described in [Chart 74-7](#).
- Teach the patient who is going home after a hysterectomy how to monitor for infection or other complications.
- Instruct patients receiving external beam radiation to the abdomen to gently wash the area; to not apply creams or lotions (unless prescribed by the radiologist); to not wash off marking; to avoid exposing the area to sunlight or temperature extremes; and to wear soft, nonirritating clothing.

Care of Male Patients with Reproductive Problems

Concept Map: Benign Prostatic Hyperplasia (BPH)
Key Points
Review Questions for the NCLEX® Examination

LEARNING OUTCOMES

Safe and Effective Care Environment

1. Identify health care team members to provide collaborative care and discharge planning for patients with male reproductive problems.

Health Promotion and Maintenance

2. Teach men and their partners about community resources for reproductive cancers.
3. Evaluate patient risk factors for male reproductive cancers.
4. Develop a health teaching plan for men to prevent or detect early male reproductive cancers.

Psychosocial Integrity

5. Assess the patient's acceptance of body image changes that may result from male reproductive surgery.
6. Explain the psychosocial needs of men who have male reproductive problems.

Physiological Integrity

7. Perform a focused physical assessment of the man's reproductive system.
8. Describe the mechanisms of action, side effects, and nursing implications for pharmacologic management of benign prostatic hyperplasia (BPH).

9. Develop a postoperative plan of care for a patient undergoing surgery for benign prostatic hyperplasia.
10. Incorporate complementary and alternative therapies into the patient's plan of care.
11. Discuss treatment options for prostate cancer with patients, partners, and/or families.
12. Provide preoperative teaching for patients having a radical prostatectomy.
13. Develop a teaching plan for the patient and family about the role of drug therapy in treating prostate cancer.
14. Identify adverse effects of radiation therapy for reproductive cancers.
15. Develop a community-based plan of care for a man with prostate cancer.
16. Describe the options for treating erectile dysfunction.
17. Discuss cultural considerations related to male reproductive problems.
18. Develop a plan of care for a patient with testicular cancer, including fertility issues.
19. Compare the assessment and treatment for hydrocele, spermatocele, and varicocele.

Male reproductive problems can range from short-term infections to long-term health care problems that may require end-of-life care. Any health issue that affects the male reproductive system can affect the human need for *sexuality*. For example, some patients have surgeries that damage essential

nerves that are needed to have an erection. Others have disorders that psychologically prevent the patient from engaging in his usual sexual activity.

The role of the nurse and other health care team members is to be open, supportive, and nonjudgmental when caring

FIG. 75-1 Benign prostatic hyperplasia (BPH) grows inward, causing narrowing of the urethra.

for men with reproductive problems. Respect the man's privacy at all times.

BENIGN PROSTATIC HYPERPLASIA

Pathophysiology

Benign prostatic hyperplasia (BPH) is a very common health problem, but the exact cause is unclear. It is likely the result of a combination of aging and the influence of androgens that are present in prostate tissue, such as dihydrotestosterone (DHT) (McCance et al., 2010). With aging and increased DHT levels, the glandular units in the prostate undergo nodular tissue **hyperplasia** (an increase in the number of cells). This altered tissue promotes local inflammation by attracting cytokines and other substances (McCance et al., 2010).

As the prostate gland enlarges, it extends upward into the bladder and inward, causing **bladder outlet obstruction** (Fig. 75-1). In response, the urinary system is affected in several ways. First, the detrusor (bladder) muscle thickens to help urine push past the enlarged prostate gland (McCance et al., 2010). In spite of the bladder muscle change, the patient has increased residual urine (stasis) and chronic urinary retention. The increased volume of residual urine often causes **overflow urinary incontinence**, in which the urine "leaks" around the enlarged prostate causing dribbling. Urinary stasis can also result in urinary tract infections and bladder calculi (stones).

In a few patients, the prostate becomes very large and the man cannot void (acute urinary retention [AUR]). The patient with this problem requires emergent care. In other patients, chronic urinary retention may result in a backup of urine and cause a gradual dilation of the ureters (**hydronephrosis**) and kidneys (**hydronephrosis**) if BPH is not treated. These problems can lead to chronic kidney disease as described in Chapter 71.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

History

When taking a history, several standardized assessment tools are used to help the health care provider determine the severity of lower urinary tract symptoms (LUTS) associated with

prostatic enlargement. One of the most commonly used assessments is the International Prostate Symptom Score (I-PSS), which incorporates the American Urological Association Symptom Index (AUA-SI) (Fig. 75-2) as questions 1 through 7. The additional question included on the I-PSS is the effect of the patient's urinary symptoms on quality of life. Most patients complete the questions as a self-administered tool because it is available in many languages. If the patient is illiterate or does not feel like reading the questions, the nurse or health care provider can ask them. Be sure that older men wear their glasses or contact lenses, if needed.

Physical Assessment/Clinical Manifestations

Ask about the patient's current urinary pattern. Assess for urinary frequency and urgency. Determine the number of times the patient awakens during the night to void (**nocturia**). Other symptoms of LUTS include:

- Difficulty in starting (hesitancy) and continuing urination
- Reduced force and size of the urinary stream ("weak" stream)
- Sensation of incomplete bladder emptying
- Straining to begin urination
- Post-void (after voiding) dribbling or leaking

If frequency and nocturia do not occur with restricted urinary flow, the patient may have an infection or other bladder problem. Ask whether the patient has had **hematuria** (blood in the urine) when starting the urine stream or at the end of voiding. BPH is a common cause of hematuria in older men.

The advanced practice nurse or other health care provider examines the patient for physical changes of the prostate gland. Remind the patient to void before the physical examination. Inspect and palpate the abdomen for a distended bladder. The health care provider may percuss the bladder. If the patient has a sense of urgency when gentle pressure is applied, the bladder may be distended. Obese patients are best assessed by percussion or bedside ultrasound bladder scanner rather than by inspection or palpation.

Prepare the patient for the prostate gland examination. Tell him that he may feel the urge to urinate as the prostate is palpated. Because the prostate is close to the rectal wall, it is easily examined by digital rectal examination (DRE). Help the patient bend over the examination table or assume a side-lying fetal position, whichever is the easiest position for him. The health care provider examines the prostate for size and consistency. BPH presents as a uniform, elastic, nontender enlargement, whereas cancer of the prostate gland feels like a stony-hard nodule. Advise the patient that after the prostate gland is palpated, it may be massaged to obtain a fluid sample for examination to rule out **prostatitis** (inflammation and possible infection of the prostate), a common problem that can occur with BPH. If the patient has bacterial prostatitis, he is treated with broad-spectrum antibiotic therapy for at least 30 days to prevent the spread of infection (McCance et al., 2010).

Psychosocial Assessment

Patients who have nocturia and other LUTS may be irritable or depressed as a result of interrupted sleep and annoying visits to the bathroom. Assess the effect of sleep interruptions on the patient's mood and mental status.

International Prostate Symptom Score (I-PSS)

Patient Name: _____ Date of Birth: _____ Date Completed: _____

In the past month:	Not at All	Less Than 1 in 5 Times	Less Than Half the Time	About Half the Time	More Than Half the Time	Almost Always	Your Score

FIG. 75-2 The International Prostate Symptom Score (I-PSS).

Continued

About the I-PSS

The International Prostate Symptom Score (I-PSS) is based on the answers to seven questions concerning urinary symptoms and one question concerning quality of life. Each question concerning urinary symptoms allows the patient to choose one out of six answers indicating increasing severity of the particular symptom. The answers are assigned points from 0 to 5. The total score can therefore range from 0 to 35 (asymptomatic to very symptomatic).

The questions refer to the following urinary symptoms:

Questions	Symptom
1	Incomplete emptying
2	Frequency
3	Intermittency
4	Urgency
5	Weak Stream
6	Straining
7	Nocturia

Question 8 refers to the patient's perceived quality of life.

The first seven questions of the I-PSS are identical to the questions appearing on the American Urological Association (AUA) Symptom Index, which currently categorizes symptoms as follows:

- Mild (symptom score less than or equal to 7)
- Moderate (symptom score range 8 to 19)
- Severe (symptom score range 20 to 35)

The International Scientific Committee (SCI), under the patronage of the World Health Organization (WHO) and the International Union Against Cancer (UICC), recommends the use of only a single question to assess the quality of life. The answers to this question range from "delighted" to "terrible," or 0 to 6. Although this single question may or may not capture the global impact of benign prostatic hyperplasia (BPH) symptoms or quality of life, it may serve as a valuable starting point for a doctor-patient conversation.

The SCI has agreed to use the symptom index for BPH, which has been developed by the AUA Measurement Committee, as the official worldwide symptoms assessment tool for patients suffering from prostatism.

The SCI recommends that physicians consider the following components for a basic diagnostic workup: history; physical examination; appropriate labs such as U/A, creatinine, etc.; and DRE or other evaluation to rule out prostate cancer.

FIG. 75-2, cont'd

Post-void dribbling and overflow incontinence may cause embarrassment and prevent the patient from socializing or leaving his home. For some patients, this social isolation can affect quality of life and lead to clinical depression and/or severe anxiety. Johnson et al. (2010) found a strong correlation between depression and BPH in older men. Depressed patients were three times more likely to have severe symptoms.

Laboratory Assessment

A urinalysis and culture are typically obtained to diagnose urinary tract infection and microscopic hematuria. If infection is present, the urinalysis measures the number of white blood cells (WBCs).

Other laboratory studies that may be performed include:

- A complete blood count (CBC) to evaluate any evidence of systemic infection (elevated WBCs) or anemia (decreased red blood cells [RBCs]) from hematuria
- Blood urea nitrogen (BUN) and serum creatinine levels to evaluate renal function (both are usually elevated with kidney disease)
- A prostate-specific antigen (PSA) and a serum acid phosphatase level if prostate cancer is suspected (both are typically elevated in patients who have prostate cancer)
- Culture and sensitivity of prostatic fluid (if expressed during the examination)

Other Diagnostic Assessment

Imaging studies that are typically performed are *transabdominal ultrasound* and *transrectal ultrasound (TRUS)*. The patient having a TRUS lies on his side while the transducer is inserted into the rectum for viewing the prostate and surrounding structures. A tissue biopsy may also be done if the health care provider is uncertain whether the prostatic problem is benign or malignant.

In some cases, the physician uses a cystoscope to view the interior of the bladder, the bladder neck, and the urethra. This examination is used to study the presence and effect of bladder neck obstruction. The procedure is usually done in an ambulatory care setting. See Chapter 69 for a detailed description of *cystoscopy* and the nursing care needed for patients having this procedure.

Residual urine may be determined by *bladder ultrasound* immediately after the patient voids. As an alternative, because the patient voids before cystoscopy, residual urine may be measured when the cystoscope is inserted. *Urodynamic pressure-flow studies* may help diagnose and grade bladder outlet obstruction and detrusor muscle function.

ANALYSIS

The priority problem for the patient with benign prostatic hyperplasia (BPH) is Impaired Urinary Elimination related to bladder outlet obstruction.

PLANNING AND IMPLEMENTATION

Improving Urinary Elimination

Planning: Expected Outcomes. The patient with BPH is expected to have a normal urinary elimination pattern without urinary hesitancy, urgency, or infection.

Interventions. Patients with symptomatic BPH are first treated with nonsurgical interventions, such as drug therapy. The Concept Map on p. 1634 shows nursing assessment and collaborative interventions for the patient with BPH.

Nonsurgical Management. Drug therapy is a popular option for treating BPH. For patients with AUR or for those who do not respond or cannot tolerate drug therapy, non-invasive procedures or surgery is the treatment of choice.

Drug Therapy. Drugs from two major categories may be used alone, but most commonly they are given in combination. The health care provider usually prescribes a *5-alpha reductase inhibitor (5-ARI)* as *first-line drug therapy*. Examples of these drugs are finasteride (Proscar) and dutasteride (Avodart). Normally, testosterone is converted to DHT in the prostate gland by the enzyme *5-alpha reductase*. By taking an enzyme-inhibiting agent, the patient's DHT levels decrease, which results in reducing the enlarged prostate.

! NURSING SAFETY PRIORITY

Drug Alert

Remind patients who are being treated with a 5-ARI for BPH that they may need to take it for as long as 6 months before improvement is noticed. Teach them about possible side effects, which include erectile dysfunction (ED), decreased libido (sexual desire), and dizziness due to orthostatic hypotension. Remind them to change positions carefully and slowly.

The alpha-adrenergic receptors in prostatic smooth muscle enable the prostate gland to respond to *alpha-1 selective*

blocking agents, such as tamsulosin (Flomax), alfuzosin (Uroxatral), doxazosin (Cardura, Cardura-1 ♣), terazosin (Hytrin), and silodosin (Rapaflo). Tamsulosin is also available as an over-the-counter (OTC) drug. These drugs relax smooth muscles in the prostate gland, creating less urinary resistance and improved urinary flow. They also cause peripheral vasodilation and reduced peripheral vascular resistance.

! NURSING SAFETY PRIORITY

Drug Alert

If giving alpha blockers in an inpatient setting, assess for orthostatic (postural) hypotension, tachycardia, and syncope ("blackout"), especially after the first dose is given to older men. If the patient is taking the drug at home, teach him to be careful when changing position and to report any weakness, lightheadedness, or dizziness to the health care provider immediately. Bedtime dosing may decrease the risk for problems related to hypotension. Drugs used to treat erection problems (e.g., Viagra) can worsen these side effects. Teach patients taking a 5-ARI or alpha blocking drug to keep all appointments for follow-up laboratory testing because both drug classes can cause liver dysfunction.

The most effective drug therapy approach for many patients is a combination of a 5-ARI drug and an alpha-1 selective blocking agent. A commonly prescribed drug regimen is finasteride and doxazosin. Newer drugs, such as Jalyn, provide a combination of dutasteride and tamsulosin in a once-a-day capsule.

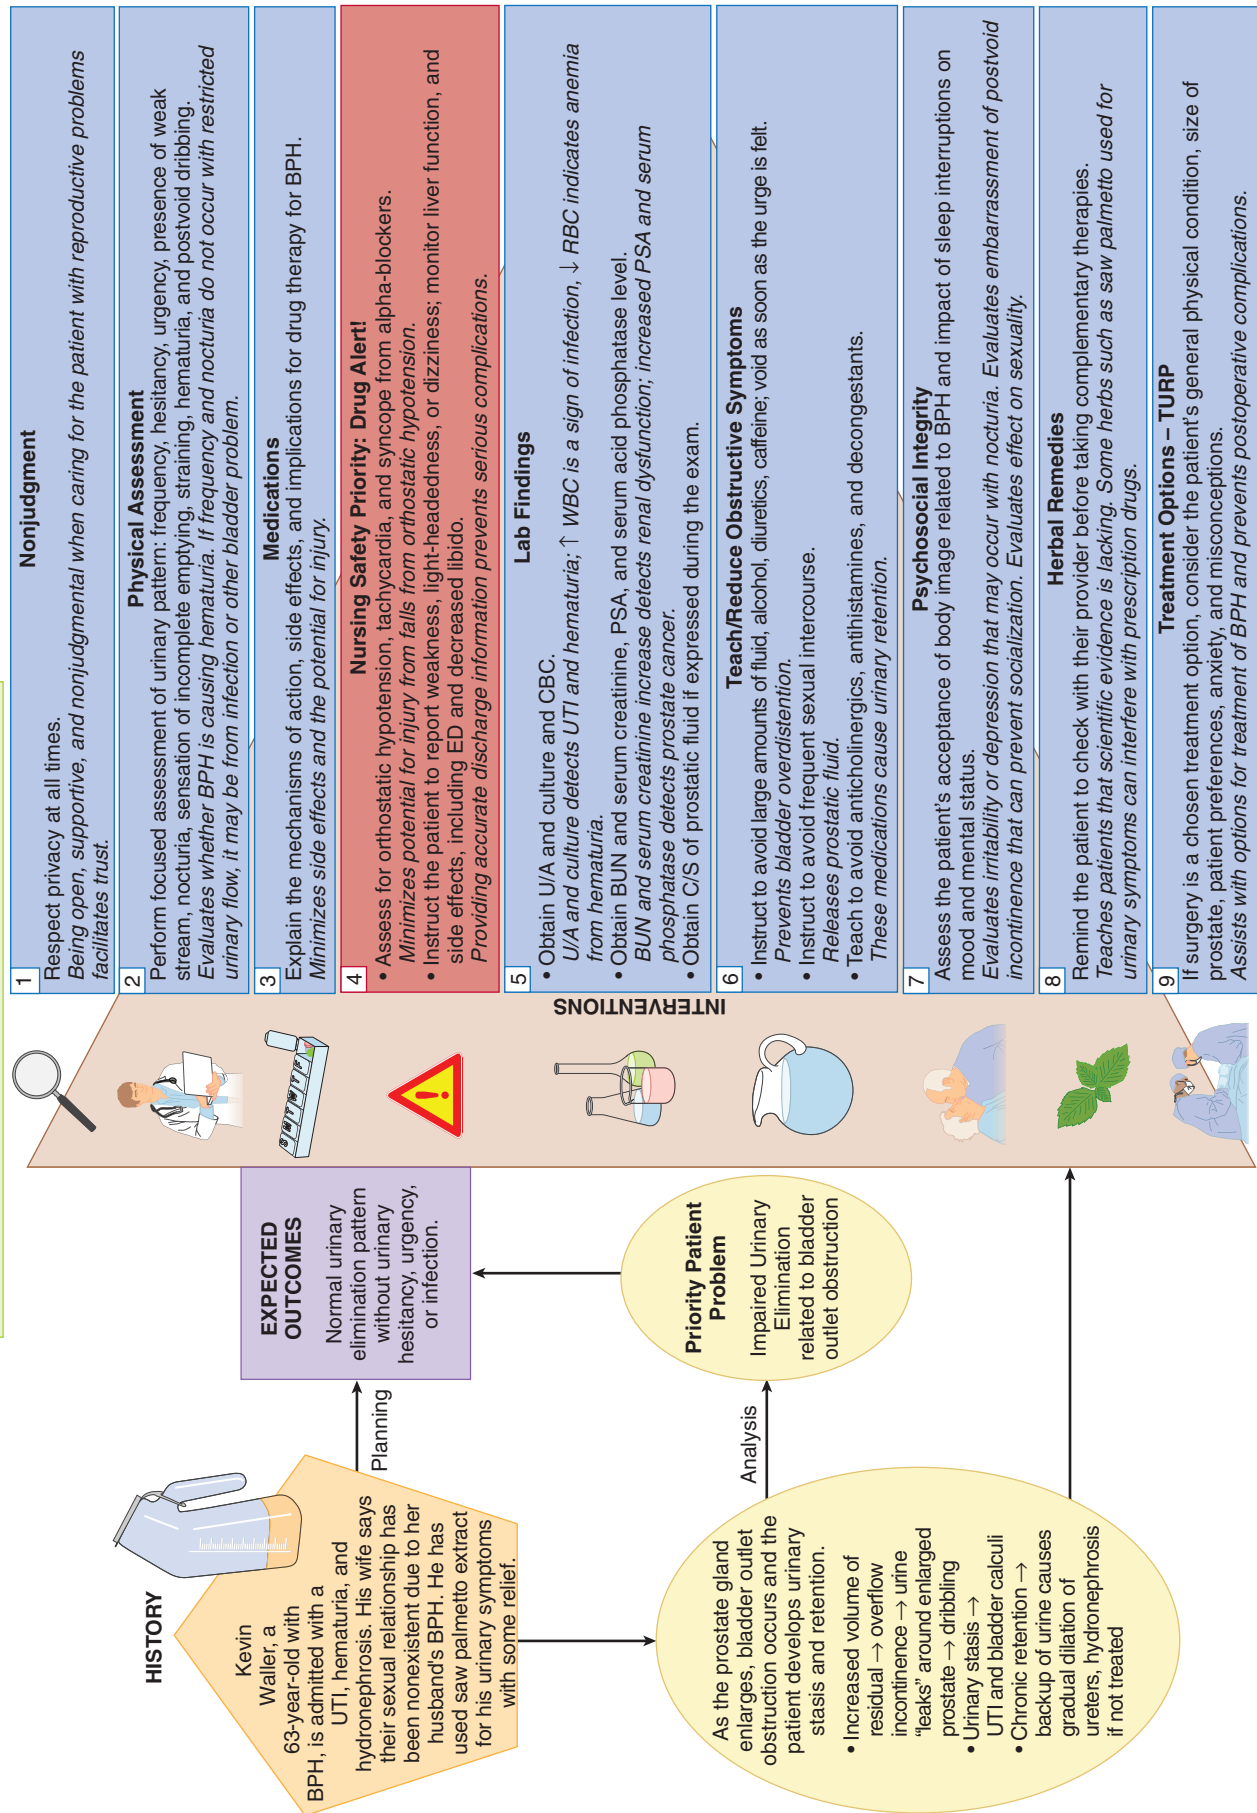

Other drugs may be helpful in managing specific urinary symptoms. For example, low-dose oral desmopressin, a synthetic antidiuretic analog, has been used successfully for nocturia (Wang et al., 2011). Drugs being tested for their effectiveness in treating BPH include bisphosphonates, ezetimibe (Zetia), Botox, and Nymox.

Complementary and Alternative Therapies. Although many men use *Serenoa repens* (saw palmetto extract), a plant extract, to help manage the urinary symptoms associated with BPH, studies on the effectiveness of this herb have not shown that it is effective (Tackland et al., 2009). Teach patients who want to try these herbs and other natural substances that scientific evidence to prove they are useful is lacking. However, if they choose to take them, remind them to check with their health care provider before taking any OTC natural substance. Some herbs interfere with prescription drugs the patient may be taking for other health problems. Side effects, such as abdominal pain, nausea, and vomiting, are mild, reversible, and infrequent (Agbabiaka et al., 2009).

Other Nonsurgical Interventions. Other interventions that may reduce obstructive symptoms include those that cause the release of prostatic fluid such as frequent sexual intercourse. This approach is helpful for the man whose obstructive symptoms result from an enlarged prostate with a large amount of retained prostatic fluid.

Teach patients with BPH to avoid drinking large amounts of fluid in a short time; to avoid alcohol, diuretics, and caffeine; and to void as soon as they feel the urge. These measures are aimed at preventing overdistention of the bladder, which may result in loss of detrusor muscle tone. Teach patients to avoid any drugs that can cause urinary retention, especially anticholinergics, antihistamines, and decongestants. Emphasize the importance of telling any health care

Concept Map: Benign Prostatic Hyperplasia (BPH)

provider about the diagnosis of BPH so that these drugs are not prescribed.

If drug therapy or other measures are not helpful in relieving urinary symptoms, several noninvasive techniques are available to destroy excess prostate tissue using a variety of heat methods (**thermotherapy**). These procedures are often done in a physician's office or another ambulatory care setting. Examples include:

- **Transurethral needle ablation (TUNA)** (low radio-frequency energy shrinks the prostate)
- **Transurethral microwave therapy (TUMT)** (high temperatures heat and destroy excess tissue)
- **Interstitial laser coagulation (ILC)**, also called **contact laser prostatectomy (CLP)** (laser energy coagulates excess tissue)
- **Electrovaporization of the prostate (EVAP)** (high-frequency electrical current cuts and vaporizes excess tissue)

Prostatic stents may be placed into the urethra to maintain permanent patency after a procedure for destroying or removing prostatic tissue. All of these highly technical treatments use local or regional anesthesia and do not require an indwelling urinary catheter. They are also associated with less risk for complications such as intraoperative bleeding and erectile dysfunction when compared with traditional surgical approaches. Patients can return to their usual activities in a day or two.

Surgical Management. For patients who are not candidates for nonsurgical management or do not want to take drugs or have other treatment options, surgery may be performed. The gold standard continues to be a **transurethral resection of the prostate (TURP)** in which the enlarged portion of the prostate is removed through an endoscopic instrument. The newer holmium laser enucleation of the prostate (HoLEP) procedure is a minimally invasive surgical technique that is gaining popularity. For a few men, an open prostatectomy (entire prostate removal) may be performed (see discussion of Surgical Management on p. 1639 in the Prostate Cancer section). Some or all of these criteria indicate the need for surgery:

- Acute urinary retention (AUR)
- Chronic urinary tract infections secondary to residual urine in the bladder
- Hematuria
- Hydronephrosis

Preoperative Care. When planning surgical interventions, the patient's general physical condition, the size of the prostate gland, and the man's preferences are considered. The patient may have many fears and misconceptions about prostate surgery, such as believing that automatic loss of sexual functioning or permanent incontinence will occur. Assess the patient's anxiety, correct any misconceptions about the surgery, and provide accurate information to him and his family. Regardless of the type of surgery to be performed, provide information about anesthesia (see Chapter 17). The patient may have other medical problems that increase the risk for complications of general anesthesia and may be advised to have regional anesthesia. Epidural and spinal anesthesia are the most common types of anesthesia used for a TURP. Because the patient is awake, it is easier to assess for hyponatremia (low serum sodium), fluid overload, and water intoxication, which can result from large bladder irrigations.

In **transurethral resection of the prostate (TURP)**, the surgeon inserts a resectoscope through the urethra and into the bladder and removes pieces of tissue from the prostate gland.

FIG. 75-3 Transurethral resection of the prostate procedure used for benign prostatic hyperplasia.

After a TURP, all patients have an indwelling urethral catheter for at least a day. *Be sure that they know that they will feel the urge to void while the catheter is in place.* Tell the patient that he will likely have traction on the catheter that may cause discomfort. However, reassure him that analgesics will be prescribed to relieve his pain. Explain that it is normal for the urine to be blood-tinged after surgery. Small blood clots and tissue debris may pass while the catheter is in place and immediately after it is removed.

Operative Procedures. The traditional TURP is a “closed” surgery. To perform the procedure, the surgeon inserts a resectoscope (an instrument similar to a cystoscope, but with a cutting and cauterizing loop) through the urethra (Fig. 75-3). The enlarged portion of the prostate gland is then removed in small pieces (prostate chips). A similar procedure is the transurethral incision of the prostate (TUIP), in which small cuts are made into the prostate to relieve pressure on the urethra. This alternate technique is used for smaller prostates. To prevent bleeding and excess clotting, a fibrinolytic inhibitor like tranexamic acid (Cyklokapron) may be used during surgery.

The disadvantage of a TURP is that, because only small pieces of the gland are removed, remaining prostate tissue may continue to grow and cause urinary obstruction, requiring additional TURPs. Also, urethral trauma from the resectoscope with resulting urethral strictures is possible.

In many large medical centers around the world, specialists can perform newer surgical treatments, such as the **holmium laser enucleation of the prostate (HoLEP)** (Eltabey et al., 2010). For this procedure, the surgeon uses the laser to remove the obstructive prostatic tissue and push it into the bladder for removal and seals all blood vessels. Very little blood is lost during the short procedure and is therefore safe for patients taking anticoagulants.

Postoperative Care. After both the TURP and HoLEP procedures, a urinary catheter is placed into the bladder. Traction is often applied on the catheter for the patient having a TURP by pulling it taut and taping it to the patient's abdomen or

CHART 75-1 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Care of the Patient After Transurethral Resection of the Prostate

- Monitor the patient closely for signs of infection. Older men undergoing prostate surgery often also have underlying chronic diseases (e.g., cardiovascular disease, chronic lung disease, diabetes).
- Help the patient out of the bed to the chair as soon as permitted to prevent complications of immobility. Older men may need assistance because of underlying changes in the musculoskeletal system (e.g., decreased range of motion, stiffness in joints). These patients are at *high risk* for falls.
- Assess the patient's pain every 2 to 4 hours, and intervene as needed to control pain.
- Provide a safe environment for the patient. Anticipate a temporary change in mental status for the older patient in the immediate postoperative period as a result of anesthetics and unfamiliar surroundings. Reorient the patient frequently. Keep catheter tubes secure.
- Use normal saline solution for the bladder irrigant unless otherwise prescribed. Normal saline solution is isotonic.
- Monitor the color, consistency, and amount of urine output.
- Check the drainage tubing frequently for external obstructions (e.g., kinks) and internal obstructions (e.g., blood clots, decreased output).
- Assess the patient for reports of severe bladder spasms with decreased urinary output, which may indicate obstruction.
- If the urinary catheter is obstructed, irrigate the catheter per agency or surgeon protocol.
- Notify the physician immediately if the obstruction does not resolve by hand irrigation or if the urinary return becomes ketchup-like.

thigh. If the catheter is taped to the patient's thigh, instruct him to keep his leg straight. The patient having the HoLEP procedure has a urinary catheter overnight, but the patient with a TURP has a catheter in place for several days. In some cases, the patient is discharged with the catheter in place.

CONSIDERATIONS FOR OLDER ADULTS

When caring for older men who may become confused after surgery, reorient them frequently and remind them not to pull on the catheter. If the patient is restless or "picks" at tubes, provide a familiar object such as a family picture for him to hold for distraction and a feeling of security. Do not restrain the patient unless all other alternatives have failed.

Remind the patient that because of the urinary catheter's large diameter and the pressure of the retention balloon on the internal sphincter of the bladder, he will feel the urge to void continuously. This is a normal sensation, not a surgical complication. Advise the patient not to try to void around the catheter, which causes the bladder muscles to contract and may result in painful spasms. [Chart 75-1](#) summarizes the nursing care for patients having a TURP.

When the urinary catheter is removed, the patient may experience burning on urination and some urinary frequency, dribbling, and leakage. Reassure him that these symptoms are normal and will decrease. The patient may also pass small clots and tissue debris for several days after the TURP. *Instruct him to increase fluid intake to at least 2000 to 2500 mL daily, which helps decrease dysuria and keep the urine clear. An older*

! NURSING SAFETY PRIORITY

Critical Rescue

After a TURP, monitor the patient's urine output every 2 hours and vital signs, including pain assessment, every 4 hours for the first postoperative day. Assess for postoperative bleeding. *Patients who undergo a TURP or open prostatectomy are at risk for severe bleeding or hemorrhage after surgery. Although rare, bleeding is most likely within the first 24 hours.* Blood transfusions are commonly given after a TURP surgery but are not needed after the HoLEP procedure. Bladder spasms or movement may trigger fresh bleeding from previously controlled vessels. This bleeding may be arterial or venous, but venous bleeding is more common.

If the bleeding is arterial, the urinary drainage is bright red or ketchup-like with numerous clots. If arterial bleeding occurs, notify the surgeon immediately, and irrigate the catheter with normal saline solution per physician or hospital protocol. In rare instances, the surgeon may prescribe aminocaproic acid (Amicar) to control bleeding. If this drug does not work, surgical intervention may be needed to clear the bladder of clots and to stop bleeding.

If the bleeding is venous, the urine output is burgundy, with or without any change in vital signs. Inform the surgeon of any bleeding. Closely monitor the patient's hemoglobin (Hgb) and hematocrit (Hct) levels for anemia as a result of blood loss.

patient who has renal disease or who is at risk for heart failure may not be able to tolerate this much fluid. By the time of discharge (usually 2 to 3 days after surgery), he should be voiding 150 to 200 mL of clear yellow urine every 3 to 4 hours. By discharge, pain is minimal and analgesics may not be required.

Observe for other possible but uncommon complications of TURP, such as infection and incontinence. Teach the patient that sexual function should not be affected after surgery but that **retrograde ejaculation** is possible. In this case, most of the semen flows backwards into the bladder so only a small amount will be ejaculated from the penis.

Community-Based Care

The patient with benign prostatic hyperplasia (BPH) is typically managed at home. Patients who have surgery are also discharged to their home or other setting from where they were admitted. Some patients, especially those who have had a TURP, may have temporary loss of control of urination or a dribbling of the urine. Reassure the patient that these symptoms are almost always temporary and will resolve. Assist the patient and his family in finding ways to keep his clothing dry until sphincter control returns. Instruct him to contract and relax his sphincter frequently to re-establish urinary control (Kegel exercises). External urinary (condom) catheters are not used except in extreme cases because they may give the patient a false sense of security and delay urinary control.

? NCLEX EXAMINATION CHALLENGE

Physiological Integrity

A client had a transurethral resection of the prostate (TURP) yesterday. The staff nurse notes that the hemoglobin is 8.2 g/dL. What is the nurse's best action?

- Notify the charge nurse as soon as possible.
- Irrigate the catheter with 30 mL normal saline.
- Document the assessment in the medical record.
- Prepare for a blood transfusion.

FIG. 75-4 The prostate gland with cancer and benign prostatic hyperplasia (BPH). Note that cancer normally arises in the periphery of the gland, whereas BPH occurs in the center of the gland.

Patients having the HoLEP procedure typically stay in the hospital overnight and usually have no urinary symptoms after surgery. This procedure may soon replace the TURP as the gold standard for surgical management of the patient with BPH.

PROSTATE CANCER

Pathophysiology

Prostate cancer is one of the most common types of cancer in men in the world. Men older than 65 years have the greatest risk for the disease. In the United States, it affects African-American men more commonly than Euro-American men and at an earlier age. The exact cause for this difference is not known.

Testosterone and dihydrotestosterone (DHT) are the major androgens (male hormones) in the adult male. Testosterone is produced by the testis and circulates in the blood. DHT is a testosterone derivative in the prostate gland. In some patients, the prostate grows very rapidly, leading to noncancerous high-grade prostatic intraepithelial neoplasia (PIN). Patients with PIN are at a higher risk for developing prostate cancer than men who do not have that growth pattern.

Many prostate tumors are androgen sensitive (McCance et al., 2010). Most are adenocarcinomas and arise from epithelial cells located in the posterior lobe or outer portion of the gland (Fig. 75-4).

Of all malignancies, prostate cancer is one of the slowest growing, and it metastasizes (spreads) in a predictable pattern. Common sites of metastasis are the nearby lymph nodes, bones, lungs, and liver (McCance et al., 2010). The bones of the pelvis, sacrum, and lumbar spine are most often affected. Chapter 23 describes staging categories of localized and advanced cancers.

Prostate cancer is likely caused by a number of factors, including androgens. Dietary factors, such as eating a diet high in animal fat (e.g., red meat) and complex carbohydrates or having a low fiber intake, increase the risk for prostate cancer. Men who have had a vasectomy or those who were

exposed to environmental toxins, such as arsenic, may also be at increased risk for the disease (Held-Warmkessel, 2008; McCance et al., 2010).

GENETIC/GENOMIC CONSIDERATIONS

Many gene mutations play a role in various types of prostate cancer. Some men with the most aggressive prostate cancers have *BRCA2* mutations similar to those women who have *BRCA2*-associated breast and ovarian cancers. The most common genetic factor that increases the risk for prostate cancer is a mutation in the glutathione S-transferase (*GST P1*) gene. This gene is normally part of the pathway that helps prevent cancer (McCance et al., 2010).

Health Promotion and Maintenance

Teach men about the most recent American Cancer Society (ACS) guidelines for prostate cancer screening and early detection (ACS, 2011). The current recommendations are that men should make an informed decision about whether to have prostate cancer screening. Starting at the age of 50, men should discuss the options of having prostate-specific antigen testing with their health care provider. Men at a higher risk for prostate cancer, including African Americans or men who have a first-degree relative with prostate cancer before the age of 65, should have this discussion at age 45. Men who have multiple first-degree relatives with prostate cancer at an early age should discuss screening at age 40.

Although a family history of prostate cancer cannot be changed, certain nutritional habits can be altered to possibly decrease the risk for the disease. First, teach men to eat a healthy, balanced diet, including decreasing animal fat (e.g., red meat). Instead of red meat, remind them to eat more fish and other foods high in *omega-3 fatty acids* because they are thought to be helpful in preventing cancer. Also reinforce the need to increase fruits, vegetables, soy, and high-fiber foods.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

History

Assess the patient's age, race/ethnicity, and family history of prostate cancer. Ask about his nutritional habits, especially focusing on the intake of red meat, fish, and fruits and vegetables. Assess whether the patient has any problems with urination. Take a drug history to determine if he is taking any medication that could affect voiding. The first symptoms that the man may report are related to bladder outlet obstruction, such as difficulty in starting urination, frequent bladder infections, and urinary retention. Ask about urinary frequency, **hematuria** (blood in the urine), and **nocturia** (voiding during the night). Ask if he has had any pain during intercourse, especially when ejaculating. Inquire if the patient has had or currently has any other pain (particularly bone pain), a symptom associated with advanced prostate cancer. Ask him if he has had any recent unexpected weight loss.

Take a sexual history for recent changes in desire or function. Ask about current or previous sexually transmitted diseases, penile discharge, or scrotal pain or swelling.

Physical Assessment/Clinical Manifestations

Most *early* cancers are diagnosed while the patient is having a routine physical examination or is being treated for benign prostatic hyperplasia (BPH). Gross blood in the urine (hematuria) is a common clinical manifestation of *late* prostate cancer. Assess for pain in the pelvis, spine, hips, or ribs. Complete a thorough pain assessment. Palpate for swollen lymph nodes, especially in the groin areas. Pain and swollen nodes also indicate advanced disease that has spread. Take and record the patient's weight because unexpected weight loss is also common when the disease is advanced.

Prepare the patient for a digital rectal examination (DRE). On rectal examination, a prostate that is found to be stony hard and with palpable irregularities or indurations is suspected to be malignant.

Psychosocial Assessment

A diagnosis of any type of cancer causes fear and anxiety for most people. Some men, particularly African Americans, develop the disease in their 40s and 50s when they are perhaps planning their retirements, putting their children through college, and/or enjoying their middle years. Assess the reaction of the patient to the diagnosis, and observe how his family reacts to the illness. Men may describe their feelings as shock, fear, anger, and “roller coaster” (Wallace & Storms, 2007). Expect that patients will go through the grieving process and may be in denial or depressed. Determine what support systems they have, such as spiritual leaders or community group support, to help them through diagnosis, treatment, and recovery.

One of the biggest concerns for the man may be his ability for sexual function after cancer treatment. Tell him that function will depend on the type of treatment he has. Most surgical techniques used today do not involve cutting the perineal nerves that are needed for an erection. A dry climax may occur if the prostate is removed because it produces most of the fluid in the ejaculate. Refer the patient to his surgeon (urologist), sex therapist, or intimacy counselor if available.

Laboratory Assessment

Prostate-specific antigen (PSA) is a glycoprotein produced by the prostate. *PSA analysis is used as a screening test for prostate cancer.* If the test is performed, it should be drawn before the DRE because the examination can cause an increase in PSA due to prostate irritation.

The normal blood level of PSA in men younger than 50 years is less than 2.5 ng/mL. PSA levels increase to as high as 6.5 ng/mL when men reach their 70s. *African-American men have a slightly higher normal value, but the reason for this difference is not known. Because other prostate problems also increase the PSA level, it is not specifically diagnostic for cancer.* The level associated with prostate cancer, however, is usually much higher than those occurring with problems such as prostatitis and benign prostatic hyperplasia (Pagana & Pagana, 2010).

An elevated PSA level should decrease a few days after a prostatectomy for cancer. An increase in the PSA level several weeks after surgery usually indicates that the disease has recurred.

Because PSA is not absolutely specific to prostate cancer, another test, *early prostate cancer antigen (EPCA-2)*, may be

a serum marker for prostate cancer. It can detect changes in the prostate gland early and is a very sensitive test. EPCA-2 may also eliminate the need to perform a biopsy of prostate tissue.

Other Diagnostic Assessment

After assessments by DRE and PSA, most patients have a *transrectal ultrasound (TRUS)* of the prostate in an ambulatory care or imaging setting. The practitioner inserts a small probe into the rectum and obtains a view of the prostate using sound waves. If prostate cancer is suspected, a *biopsy* is usually performed to obtain an accurate diagnosis.

! NURSING SAFETY PRIORITY

Action Alert

After a *transrectal ultrasound with biopsy*, instruct the patient about possible complications, although rare, including hematuria with clots, signs of infection, and perineal pain. Teach him to report fever, chills, bloody urine, and any difficulty voiding. Advise him to avoid strenuous physical activity and to drink plenty of fluids, especially in the first 24 hours after the procedure. Teach him that a small amount of bleeding turning the urine pink is expected during this time.

After prostate cancer is diagnosed, the patient has additional imaging and blood studies to determine the extent of the disease. Common tests include lymph node biopsy, computed tomography (CT) of the pelvis and abdomen, and magnetic resonance imaging (MRI) to assess the status of the pelvic and para-aortic lymph nodes. A radionuclide bone scan may be performed to detect metastatic bone disease. An enlarged liver or abnormal liver function study results indicate possible liver metastasis.

Patients with advanced prostate cancer often have *elevated* levels of *serum acid phosphatase*. Most men with bone metastasis have *elevated serum alkaline phosphatase* levels.

INTERVENTIONS

As with any cancer, accurate staging and grading of prostate tumors guide treatment planning and monitoring during the course of the disease. Patients are faced with several treatment options. A urologist and oncologist are needed to help patients make the best decision. Because prostate cancer is slow growing with late metastasis, older men who are asymptomatic and have other illnesses may choose observation without immediate active treatment, especially if the cancer is early stage. This option is known as “watchful waiting,” or *expectant therapy*. This form of treatment involves initial surveillance with active treatment if the symptoms become bothersome. The average time from diagnosis to start of treatment is up to 10 years. During the watchful waiting period, men are monitored at regular intervals through DRE and PSA testing. Factors that are considered in choosing watchful waiting include potential side effects of treatment (e.g., urinary incontinence, erectile dysfunction), estimated life expectancy, and the risk for increased morbidity and mortality from not seeking active treatment.

Patients who have very early-stage cancer of the prostate who choose watchful waiting require close follow-up by their health care provider. If obstruction occurs, a transurethral resection of the prostate (TURP) may be done. The care of patients having this procedure is described in the discussion

of [Surgical Management](#) on p. 1635 in the [Benign Prostatic Hyperplasia](#) section.

Specific management is based on the extent of the disease and the patient's physical condition. The patient may undergo surgery for a biopsy, staging and removal of the tumor, or palliation to control the spread of disease or relieve distressing symptoms. As with watchful waiting, the health care provider and patient must weigh the benefits of treatment against potential adverse effects such as incontinence and erectile dysfunction (ED).

Surgical Management

Surgery is the most common intervention for a cure. Minimally invasive surgery (MIS) or an open surgical technique for radical prostatectomy (prostate removal) is most often performed. A [bilateral orchiectomy](#) (removal of both testicles) is another palliative surgery that slows the spread of cancer by removing the main source of testosterone.

Preoperative Care. Preoperative care depends on the type of surgery that will be done. Minimally invasive surgery (MIS) is most appropriate for localized prostate cancer and is used as a curative intervention. The most common procedure is the *laparoscopic radical prostatectomy (LRP)*, with or without robotic assistance ([Strief, 2008](#)). Other newer procedures include transrectal high-intensity focused ultrasound (HIFU) and cryosurgery. Patients who qualify for LRP must have a PSA less than 10 ng/mL and have no previous hormone therapy or abdominal surgeries. Remind the patient that the advantages of this procedure over open surgery are:

- Decreased hospital stay (1 to 2 days)
- Minimal bleeding
- Smaller or no incisions and less scarring
- Less postoperative discomfort
- Decreased time for urinary catheter placement
- Fewer complications
- Faster recovery and return to usual activities
- Nerve-sparing advantages

For the patient undergoing an *open* radical prostatectomy, provide preoperative care as for any patient having surgery (see [Chapter 16](#)).

Operative Procedures. For the *LRP procedure*, the urologist makes one or more small punctures or incisions into the abdomen. A laparoscope with a camera on the end is inserted through one of the incisions while other instruments are inserted into the other incisions. The robotic system may be used to control the movement of the instruments by a remote device. The prostate is removed along with nearby lymph nodes.

The *open* radical prostatectomy can be performed via several surgical approaches, depending on the patient's desired outcomes and the staging of the disease. The transperineal and retropubic (nerve-sparing) approaches are most commonly used. The surgeon removes the entire prostate gland along with the prostatic capsule, the cuff at the bladder neck, the seminal vesicles, and the regional lymph nodes. The remaining urethra is connected to the bladder neck. The removal of tissue at the bladder neck allows the seminal fluid to travel upward into the bladder rather than down the urethral tract, resulting in retrograde ejaculations. The patient is sterile and has little ejaculate fluid. If the surgery spares the perineal nerves, the patient often experiences temporary erectile dysfunction (ED) for many months. For men who do not

CHART 75-2 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Care of the Patient After an Open Radical Prostatectomy

- Encourage the patient to use patient-controlled analgesia (PCA) as needed.
- Help the patient get out of bed into a chair on the night of surgery and ambulate by the next day.
- Maintain the sequential compression device until the patient begins to ambulate.
- Monitor the patient for deep vein thrombosis and pulmonary embolus.
- Keep an accurate record of intake and output, including Jackson-Pratt or other drainage device drainage.
- Keep the urinary meatus clean using soap and water.
- Avoid rectal procedures or treatments.
- Teach the patient how to care for the urinary catheter because he may be discharged with the catheter in place.
- Teach the patient how to use a leg bag.
- Emphasize the importance of not straining during bowel movement. Advise the patient to avoid suppositories or enemas.
- Remind the patient about the importance of follow-up appointments with the physician to monitor progress.

regain sexual potency but had a nerve-sparing procedure, a drug such as sildenafil (Viagra) may be helpful. ED is discussed later in this chapter.

Postoperative Care. Provide postoperative care of the patient after *open* radical prostatectomy as summarized in [Chart 75-2](#). Nursing interventions include all the typical care for a patient undergoing major surgery. Maintaining hydration, caring for wound drains (open procedure), managing pain, and preventing pulmonary complications are important aspects of nursing care (see [Chapter 18](#)).

Assess the patient's pain level, and monitor the effectiveness of pain management with opioids given as patient-controlled analgesia (PCA), a common method of delivery during the first 24 hours after surgery. Administer a stool softener if needed to prevent possible constipation from the drugs. Patients having the minimally invasive surgery have much less pain and fewer complications.

The patient has an indwelling urinary catheter to straight drainage. Monitor intake and output every shift and record, or delegate this activity to and supervise unlicensed assistive personnel (UAP). An antispasmodic may be prescribed to decrease bladder spasm induced by the indwelling urinary catheter. The time for catheter removal depends on the type of procedure that is performed and overall patient condition. Those with open surgical procedures use the catheter for 7 to 10 days or longer.

Ambulation should begin no later than the day after surgery. Provide assistance in walking the patient when he first gets out of bed. Assess for scrotal or penile swelling from the disrupted pelvic lymph flow. If this occurs, elevate the scrotum and penis and apply ice to the area intermittently for the first 24 to 48 hours.

Many patients who have the minimally invasive techniques are discharged in 1 to 3 days after surgery and can resume usual activities in about a week or two. Those who have open procedures are discharged in 2 to 3 days or longer, depending on their progress.

Remind patients that common potential long-term complications of open radical prostatectomy are urinary incontinence and erectile dysfunction (ED). *Urge incontinence* may occur because the internal and external sphincters of the bladder lie close to the prostate gland and are often damaged during the surgery. Kegel perineal exercises may reduce the severity of urinary incontinence after radical prostatectomy. Teach the patient to contract and relax the perineal and gluteal muscles in several ways. For one of the exercises, teach him to:

1. Tighten the perineal muscles for 3 to 5 seconds as if to prevent voiding, and then relax.
2. Bear down as if having a bowel movement.
3. Relax and repeat the exercise.

Show him how to inhale through pursed lips while tightening the perineal muscles and how to exhale when he relaxes. To regain urinary control, teach the patient to practice holding an object, such as a pencil, in the fold between the buttock and the thigh. He may also sit on the toilet with the knees apart while voiding and start and stop the stream several times.

Nonsurgical Management

Nonsurgical management may be an adjunct to surgery or alternative intervention if the cancer is widespread or the patient's condition or age prevents surgery. Available modalities include radiation therapy, hormonal therapy, and chemotherapy (less often).

Radiation Therapy. External or internal radiation therapy may be used in the treatment of prostate cancer or as “salvage” treatments when cancer recurs. It may also be done for palliation of the patient's symptoms.

External beam radiation therapy (EBRT) comes from a source outside the body. Patients are usually treated 5 days a week for 4 to 6 weeks. Three-dimensional conformal radiation therapy (3D-CRT) can more accurately target prostate tissue and can reduce side effects such as damage to the rectum. An advanced type of this radiation called *intensity-modulated radiation therapy* provides very high doses to the prostate. EBRT can also be used to relieve pain from bone metastasis. Teach patients that external beam radiation causes ED in many men well after the treatment is completed.

Other complications from EBRT include *acute radiation cystitis* causing persistent pain and hematuria. Symptoms are usually mild to moderate and subside in 6 weeks after treatment. Drugs to prevent urinary urgency such as tolterodine (Detrol LA) may be prescribed. Teach the patient to avoid caffeine and continue drinking plenty of water and other fluids.

Radiation proctitis (rectal mucosa inflammation) may also develop but is less likely with 3D-CRT. The man reports rectal urgency and cramping and passes mucus and blood. Teach him to report these symptoms to the health care provider. Like cystitis, this problem usually resolves in 4 to 6 weeks after the treatment stops. If proctitis occurs, teach patients to limit spicy or fatty foods, caffeine, and dairy products.

Low-dose brachytherapy (internal radiation) can be delivered by implanting low-dose radiation seeds directly into and around the prostate gland. This treatment includes ultrasonically guided interstitial or radioactive seed implantation. These procedures are done on an ambulatory care basis and

are the most cost-effective treatment for early-stage prostate cancer. Reassure the patient that the dose of radiation is low and that the radiation will not pose a hazard to himself or others. Teach him that ED, urinary incontinence, and rectal problems do occur in a small percentage of cases. Fatigue is also common and may last for several months after the treatment stops. [Chapter 24](#) describes general nursing care for patients having radiation therapy.

Drug Therapy. Drug therapy may consist of either hormonal therapy (androgen deprivation therapy [ADT]) or chemotherapy. Several vaccines to locate and destroy prostate cancer cells are being studied ([Slovin, 2008](#)).

Hormone Therapy. Because most prostate tumors are hormone dependent, patients with extensive tumors or those with metastatic disease may be managed by androgen deprivation. Luteinizing hormone–releasing hormone (LH-RH) agonists or anti-androgens can be used.

Examples of *LH-RH agonists* are leuprolide (Lupron), goserelin (Zoladex), and triptorelin (Trelstar). These drugs first stimulate the pituitary gland to release the luteinizing hormone (LH). After about 3 weeks, the pituitary gland “runs out” of LH, which reduces testosterone production by the testes.

! NURSING SAFETY PRIORITY

Drug Alert

Teach patients taking LH-RH agonists that side effects include “hot flashes,” erectile dysfunction, and decreased **libido** (desire to have sex). Some men also have **gynecomastia** (breast tenderness and growth). These drugs can also cause osteoporosis. Bisphosphonates like pamidronate (Aredia) are prescribed to prevent bone fractures. They can also be used to slow the damage caused by bone metastasis.

Anti-androgen drugs, also known as *androgen deprivation therapy (ADT)*, work differently in that they block the body's ability to use the available androgens ([National Comprehensive Cancer Network \[NCCN\], 2007](#)). These drugs are the major treatment for metastatic disease. Examples include flutamide (Eulexin, Euflex ) , bicalutamide (Casodex), and nilutamide (Nilandron). These drugs inhibit tumor progression by blocking the uptake of testicular and adrenal androgens at the prostate tumor site.

Anti-androgens may be used alone or in combination with LH-RH agonists for a total or maximal androgen blockade (hormone ablation). Patients who have this drug combination often have “hot flashes” similar to those experienced by menopausal women, and they can decrease the patient's perceived quality of life. Ask the patient if he has been experiencing this problem. Megestrol acetate may be prescribed for this uncomfortable condition.

Chemotherapy. Systemic chemotherapy may be an option for patients whose cancer has spread and for whom other therapies have not worked. For example, small cell prostate cancer is rare and is more responsive to chemotherapy than to hormone therapy ([NCCN, 2007](#)). Cisplatin (Platinol) and etoposide (VP-16, VePesid) often work for this type of cancer. [Chapter 24](#) describes general nursing care for patients receiving chemotherapy.

Other Drugs. Other less commonly used drugs that are available if other drugs have failed or stopped working include

high doses of ketoconazole (Nizoral), an antifungal drug that blocks androgen production, and the female hormone *estrogen* (diethylstilbestrol or DES). Teach patients taking ketoconazole that it can cause liver and adrenal problems. Teach them to take the drug on an empty stomach and to avoid drugs such as histamine blockers and antacids, which can interfere with drug absorption (Held-Warmkessel, 2008). Patients are followed closely and have frequent laboratory tests to detect any early organ damage. The drug also interacts with many other drugs, including warfarin (Coumadin), phenytoin (Dilantin), and prednisone (Deltasone). Corticosteroids such as prednisone may be given alone as palliation to reduce pain and improve the quality of life (Held-Warmkessel, 2008).

Community-Based Care

Patient-centered collaborative care of the man with prostate cancer should include his partner, if any, and family. Recognize that the patient has specific physical and psychosocial needs that should be addressed before hospital discharge and management should continue in the community setting.

Patients with prostate cancer may require care in a wide variety of settings: at the hospital, the radiation therapy department, the oncologist's office, or home at any stage of the disease process. Specific interventions depend on which treatment the patient had or if he had a combination of treatments. This section focuses on the needs of those who had a radical prostatectomy.

Home Care Management

Discharge planning and health teaching start early, even before surgery. A patient can better plan home care management when he knows what to expect. Collaborate with the case manager to coordinate the efforts of various health care providers, surgical unit nursing staff, and possibly a home care nurse. As specified by The Joint Commission and other accrediting agencies, continuity of care is essential when caring for this patient because he may need weeks or months of therapies.

Teaching for Self-Management

An important area of teaching for the patient going home after an *open* radical prostatectomy may be urinary catheter care. An indwelling urinary catheter may be in place for up to several weeks, depending on the surgical technique that was used. Teach him and his family how to care for the catheter, use a leg bag, and identify manifestations of infection and other complications. See [Chart 75-3](#) for patient and family education.

Encourage the patient to walk short distances. Lifting may be restricted to no more than 15 pounds for up to 6 weeks, depending on the type of surgery that was done. Remind him to maintain an upright position and not walk bent or flexed. Vigorous exercise such as running or jumping should be avoided for at least 12 weeks and then gradually introduced.

Teach the patient to not strain to defecate. A stool softener may be prescribed to reduce the need for straining. If an opioid is prescribed for pain management, encourage the patient to drink adequate water to prevent constipation.

If the patient had an *open* radical prostatectomy, teach him to shower for the first 2 to 3 weeks rather than soak in a bathtub. Show patients how to inspect the incision or

CHART 75-3 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Urinary Catheter Care at Home

- Once a day, gently wash the first few inches of the catheter starting at the penis and washing outward with mild soap and water.
- Rinse and dry the catheter well.
- If you have not been circumcised, push the foreskin back to clean the catheter site; when finished, push the foreskin forward.
- Change the drainage bag at least once a week as needed:
 - Hold the catheter with one hand and the tubing with the other hand, and twist in opposite directions to disconnect.
 - Place the end of the catheter in a clean container to catch leakage of urine.
 - Remove the rubber cap from the tubing of the leg bag or clean drainage bag.
 - Clean the end of the new tubing with alcohol swabs.
 - Insert the end of the new tubing into the catheter, and twist to connect securely.
- Clean the drainage bag just removed by pouring a solution of one part vinegar to two parts water through the tubing and bag. Rinse well with water, and allow the bag to dry.

puncture site(s) daily for signs of infection. Remind them to keep all follow-up appointments. PSA blood tests are taken 6 weeks after surgery and then every 4 to 6 months to monitor progress.

Health Care Resources

Refer the patient and partner to agencies or support groups such as the American Cancer Society's Man to Man program to help cope with prostate cancer. This program provides one-on-one education, personal visits, educational presentations, and the opportunity to engage in open and candid discussions. Another prostate cancer support group is Us TOO International (www.ustoo.com) sponsored by the Prostate Cancer Education and Support Network. This group provides education and support with national and international chapters. Information can also be obtained from the Prostate Cancer Foundation (www.prostatecancerfoundation.org) or the National Prostate Cancer Coalition (www.fightprostatecancer.org). Other personal and community support

DECISION-MAKING CHALLENGE

Patient-Centered Care; Teamwork and Collaboration

An 82-year-old man is diagnosed with advanced-stage prostate cancer. His health care provider suspects bone metastasis based on the patient's report of pain in his ribs and pelvis. The patient works as a farmer in a rural community and tells you that he doesn't "care about much" since his wife died a year ago. The health care provider wants to admit him to the hospital immediately for treatment and further diagnostic testing.

1. What is your best response to the patient at this time?
2. What diagnostic testing would be appropriate for the patient at this time?
3. What possible interventions might help this patient be more comfortable?
4. With what members of the health care team might you need to collaborate?

services such as spiritual leaders or churches and synagogues are also important to many patients.

Many men have erectile dysfunction (ED) for the first 3 to 18 months after a prostatectomy. Refer them to a specialist who can help with this problem. ED is discussed in the next section (Erectile Dysfunction). Refer patients with urinary incontinence to a urologist who specializes in this area. Drug therapy and other strategies may be used. [Chapter 69](#) discusses incontinence management in detail.

ERECTILE DYSFUNCTION

Pathophysiology

Erectile dysfunction (ED), also known as *impotence*, is the inability to achieve or maintain an erection for sexual intercourse. It affects millions of men in the United States. There are two major types of ED: organic and functional.

Organic ED is a gradual deterioration of function. The man first notices diminishing firmness and a decrease in frequency of erections. Causes include:

- Inflammation of the prostate, urethra, or seminal vesicles
- Surgical procedures such as prostatectomy
- Pelvic fractures
- Lumbosacral injuries
- Vascular disease, including hypertension
- Chronic neurologic conditions, such as Parkinson disease or multiple sclerosis
- Endocrine disorders, such as diabetes mellitus (a major cause) or thyroid disorders
- Smoking and alcohol consumption
- Drugs, such as antihypertensives
- Poor overall health that prevents sexual intercourse

If the patient has episodes of ED, it usually has a *functional* (psychological) cause. Men with functional ED usually have normal nocturnal (nighttime) and morning erections. Onset is usually sudden and follows a period of high stress.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

For a man to have an erection, he must have normal innervation and a normal libido (sex drive). Therefore a medical, social, and sexual history and a complete physical examination are needed. The first step is to determine whether the cause is organic. Diagnostic testing is done to rule out possible organic causes.

If test results are negative, the evaluation then focuses on the specific causes that may have been indicated in the medical history. For example, hormone testing is used for patients who have a poor libido, small testicles, or sparse beard growth. Serum levels of *testosterone* and *gonadotropins* such as luteinizing hormone (LH) and follicle-stimulating hormone (FSH) are measured. LH stimulates the Leydig cells in the testicles to produce testosterone.

Duplex Doppler ultrasonography is another test to evaluate ED. It provides information about arterial and venous blood flow to the penis. It can also be used to determine the best treatment for ED. A *nocturnal penile tumescence test* that measures nighttime erections is done in a sleep laboratory. Usually an erection is expected with each rapid eye movement (REM)

episode. This study can determine whether ED is caused by an organic or functional problem. If the man has nocturnal erections, the ED is functional. Sex or intimacy counseling is needed in this case, and the patient is referred to a certified sex therapist or other qualified specialist.

INTERVENTIONS

The most common intervention for ED is drug therapy. Other interventions include vacuum devices, intracorporal injections, intraurethral applications, and prostheses (implants).

Drug Therapy

First-line oral drugs used to manage ED, phosphodiesterase-5 (PDE-5) inhibitors, work by relaxing the smooth muscles in the corpora cavernosa so blood flow to the penis is increased. The veins exiting the corpora are compressed, limiting outward blood flow and resulting in penile **tumescence** (swelling). Teach patients to take the pill 1 hour before sexual intercourse. For some drugs, such as sildenafil (Viagra) and vardenafil (Levitra), sexual stimulation is needed within $\frac{1}{2}$ to 1 hour to promote the erection. With other drugs, such as tadalafil (Cialis), erection can be stimulated over a longer period. Because the erection occurs more naturally compared with other treatment options, most men and their partners prefer this option.

NURSING SAFETY PRIORITY

Drug Alert

Instruct patients taking PDE-5 inhibitors to abstain from alcohol before sexual intercourse because it may impair the ability to have an erection. Common side effects of these drugs include dyspepsia (heartburn), headaches, facial flushing, and stuffy nose. If more than one pill a day is being taken, leg and back cramps, nausea, and vomiting also may occur. *Teach men who take nitrates to avoid PDE-5 inhibitors because the vasodilation effects can cause a profound hypotension and reduce blood flow to vital organs.* For patients who cannot take these drugs or do not respond to them, other methods are available to achieve an erection.

Other Interventions

The basic design of a *vacuum constriction device (VCD)* is a cylinder that fits over the penis and sits firmly against the body. Using a pump, a vacuum is created to draw blood into the penis to maintain an erection. A rubber ring (tension band) is placed around the base of the penis to maintain the erection, and the cylinder is removed.

The advantage of this procedure is that the device is easy and safe to use. The disadvantage is its clumsiness and lack of spontaneity. In addition, the man may experience pain from the rubber ring or from pumping the device too quickly. The ring should be removed after an hour, or tissue could be damaged.

Injecting the penis with vasodilating drugs can make the penis erect by engorging it with blood. The most common agents used for this purpose include):

- Alprostadil (Caverject), a synthetic vasodilator identical to prostaglandin E_1 produced in the body
- Paverine, also a vasodilator
- Phentolamine (Regitine), an alpha-1, alpha-2 selective adrenergic receptor antagonist
- A combination of any or all of these drugs

CHART 75-4 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Testicular Self-Examination

- Examine your testicles monthly immediately after a bath or a shower, when your scrotal skin is relaxed.
- Examine each testicle by gently rolling it between your thumbs and fingers. Testicular tumors tend to appear deep in the center of the testicle.
- Look and feel for any lumps; smooth, rounded masses; or any change in the size, shape, or consistency of the testes.
- Report any lump or swelling to your doctor as soon as possible.

These drugs may be injected into the side of the penis using a 27- or 30-gauge needle. Adverse effects include priapism (prolonged erection), penile scarring, fibrosis, bleeding, bruising at the injection site, pain, infection, and vasovagal responses.

Penile implants (prostheses) are used when other modalities fail. Devices include semirigid, flexible, or hydraulic inflatable and multi-component or one-piece instruments. The three-piece inflatable device is the most commonly implanted prosthesis. A reservoir is placed in the scrotum. Tubes carry the fluid into the inflatable pieces that are placed in the penis. To inflate the prosthesis, the man squeezes the pump located in the scrotum. To deflate the prosthesis, a release button is activated. Advantages include the man's ability to control his erections. The major disadvantages include device failure and infection. The device is implanted as an ambulatory surgical procedure. Teach the patient to observe the surgical site for bleeding and infection.

TESTICULAR CANCER

Pathophysiology

Testicular cancer is a rare cancer that most often affects men between 20 and 54 years of age but can affect men of any age (American Cancer Society [ACS], 2011). It usually strikes men at a productive time of life and thus has significant economic, social, and psychological impact on the patient and his family and/or partner. With early detection by testicular self-examination (TSE) (Chart 75-4) and treatment, testicular cancer can be cured. It can occur in one testicle or both.

Primary testicular cancers fall into two major groups:

- Germ cell tumors arising from the sperm-producing cells (account for most testicular cancers)
- Non-germ cell tumors arising from the stroma, interstitial, or Leydig cells that produce testosterone (account for a very small percentage of testicular cancers)

Testicular germ cell tumors are classified into two broad categories: seminomas and nonseminomas (Table 75-1). The most common type of testicular tumor is *seminoma*. Patients with seminomas have the most favorable prognoses because the tumors are usually localized, metastasize late, and respond to treatment (Bohenkamp & Yoder, 2009). They often are diagnosed when they are still confined to the testicles and retroperitoneal lymph nodes.

Non-germ cell tumors are classified as either *interstitial cell tumors* or *androblastomas* (testicular adenomas). Most of

TABLE 75-1 CLASSIFICATION OF TESTICULAR TUMORS

Germ Cell (Germinal) Tumors	Non-Germ Cell (Nongerminal) Tumors
• Seminoma • Nonseminoma: • Embryonal carcinoma • Teratoma • Choriocarcinoma	• Interstitial cell tumor • Androblastoma

these tumors do not metastasize. Interstitial cell tumors arise from the Leydig cells, which secrete testosterone into the bloodstream. Androblastomas sometimes secrete estrogen, which accounts for the feminization and **gynecomastia** (breast enlargement) occasionally seen in these men.

The risk for testicular tumors is higher in males who have an undescended testis (**cryptorchidism**) or have human immune deficiency virus (HIV) infection.

GENETIC/GENOMIC CONSIDERATIONS

Men are at a higher risk for testicular cancer if they have a family history of the disease (Hemminki et al., 2008). The incidence is higher among identical twins, brothers, and other close male relatives. Euro-American men are at a higher risk for testicular cancer than men of other races or ethnicities (Bohenkamp & Yoder, 2009). The reason for these differences is not known.

Primary testicular cancer is rarely bilateral. Other cancers such as leukemia, lymphoma, and metastatic carcinomas may invade the testes. A man with bilateral testicular tumors is more likely to have metastatic disease to the testes than primary cancer.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Physical Assessment/Clinical Manifestations

When taking a history from a patient with a suspected testicular tumor, consider the risk factors. Assess for other risk factors, including a history or presence of an undescended testis and a family history of testicular cancer.

Ask the patient whether he has noticed a discomfort such as heaviness or aching in the lower abdomen or the scrotum. Determine how long any manifestations have been present.

Assess the patient's family situation. Is the patient sexually active? If so, what is his sexual preference? Does he have children? Does he want children in the future? Depending on the treatment plan chosen, would he be interested in sperm storage in a sperm bank?

If the man has one healthy testis, he can function sexually and may not have any reproductive dysfunction. If he has a retroperitoneal lymph node dissection or chemotherapy, he may become sterile because of treatment effects on the sperm-producing cells or surgical trauma to the sympathetic nervous system resulting in retrograde ejaculations.

The testes, lymph nodes, and abdomen should be thoroughly examined. Patients may feel embarrassed about having this examination. Provide privacy, and explain the

CHART 75-5 FOCUSED ASSESSMENT

A Patient with a Testicular Lump

Obtain a medical history from the patient:

- When was the lump discovered?
- Are there any other symptoms (sensation of heaviness, dragging in testicle, pain, discharge from penis)?
- Is there a history of cryptorchidism?

Assess the genital system; always wear gloves during the examination of the male genitalia:

- Inspect and palpate the scrotal contents. Have the patient perform a Valsalva maneuver, and palpate for a varicocele.
- Any lump or enlargement that does not transilluminate should be suspected as malignant.

Palpate for any enlarged lymph nodes. The most common areas for lymphadenopathy are in the inguinal or supraclavicular regions.

Assess the abdomen for a possible mass or hepatomegaly.

procedure to the patient. *Inspect the testicles for swelling or a lump that the patient reports is painless. This is the most common manifestation of testicular cancer.* An advanced practice nurse or other health care provider palpates the testes for lumps and swelling that are not visible (Chart 75-5). The presence of any testicular pain, lymph node swelling, bone pain, abdominal masses, sudden hydrocele (fluid in the scrotum), or gynecomastia often indicates metastatic disease.

Psychosocial Assessment

Because testicular cancer and its treatment often lead to sexual dysfunction, pay close attention to the psychosocial aspects of the disease. *Sexuality* is an issue for men of any age, but it may be even more of an issue for younger men. Even if the cancer is detected at an early stage and the patient is cured after surgery, he may be afraid that he will be sexually deficient. He may also think of himself as “less than a whole person.” These fears can disrupt the psychosocial and sexual development of young males and can threaten their identity. The patient may be afraid that he will be unable to perform sexually, will no longer be sexually attractive or desirable, and will face rejection. Feelings of sexual inadequacy may be denied, repressed, or displaced, causing increased stress on the man’s personal and work relationships.

Assess the man’s support systems, including his partner, family members, and friends. Ask him where he feels that he can be supported, such as a religious or spiritual group, community club, or social group. Friends are often very helpful during this difficult time.

Laboratory Assessment

Common serum tumor markers that confirm a diagnosis of testicular cancer are:

- Alpha-fetoprotein (AFP)
- Beta human chorionic gonadotropin (hCG)
- Lactate dehydrogenase (LDH)

Serum tumor marker levels are also used to evaluate responses to therapy for testicular cancer and to document the presence of residual or recurrent disease. With effective treatment, the levels of abnormal markers fall. The persistence of elevated levels of markers after orchiectomy (testicle removal) is evidence that the patient has metastatic disease, even if x-rays and scans do not show a tumor presence. The reappearance

CHART 75-6 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Sperm Banking

- You may want to investigate sperm storage in a sperm bank as a way to preserve your sperm for future use.
- No one knows how long sperm can be stored successfully, but pregnancies have resulted from sperm stored for longer than 10 years.
- Check with the sperm bank to see how much it charges to process and store your sperm and to see whether you must pay when the service is provided.
- Investigate whether your health insurance company will reimburse you for sperm collection and storage.

of the tumor markers indicates recurrence of the cancer. Therefore marker levels must be monitored regularly during the follow-up of patients treated for testicular cancer.

Serum testosterone levels are increased when the tumor affects the Leydig cells, which produce this hormone. Drugs such as alcohol and antiepileptic drugs can also cause an increase in testosterone (Pagana & Pagana, 2010).

Other Diagnostic Assessment

When a patient has a change in testis size, shape, or texture, *ultrasonography* can determine whether the mass is solid or fluid filled. It also can help differentiate benign masses from malignant ones.

After the diagnosis of testicular cancer, the patient should have a *computed tomography (CT)* scan of the abdomen and the chest to identify small metastatic lesions. *Lymphangiography* shows a view of the body’s lymph system to look for spread to other areas.

Magnetic resonance imaging (MRI) is used to detect enlarged lymph nodes and abnormal nodules in certain organs that may indicate metastasis from the testicles. Chest x-rays and bone scans may also be performed if metastasis is suspected.

INTERVENTIONS

At diagnosis, the incidence of **oligospermia** (low sperm count) and **azoospermia** (absence of living sperm) is common in patients with testicular cancer. This problem is thought to be related to higher testicular temperatures created by cancer cell metabolism. The man may not discover that he has reduced sperm count until he has a sperm count performed before surgery.

Health teaching about reproduction, fertility, and sexuality is started in the pretreatment phase. Review the normal reproductive function, as well as the possible effects of cancer and its treatment on reproductive function. Explore with the patient various reproductive options, if desired (Chart 75-6). A sperm bank facility provides comprehensive information on semen collection, storage of semen, the storage contract, costs, and the insemination process.

When preparing the patient for the collection and storage of sperm, assume the role of patient advocate and keep in mind the effect of the cancer diagnosis. The psychological benefit of having stored sperm may be important for the man

and may influence his response to treatment. For some men, knowing that the potential for being a father still exists may help them cope with other fears, such as alopecia or erectile dysfunction (ED).

Suggest that the patient arrange for semen storage, if desired, as soon as possible after diagnosis. Sperm collection should be completed before he begins radiation therapy or chemotherapy or undergoes a radical lymph node dissection. After radiation therapy or chemotherapy has been started, the patient is at increased risk for producing mutagenic sperm, which may not be viable or may result in fetal abnormalities.

The patient's diagnosis and his physical condition may not allow treatment to be postponed, thus making sperm storage impossible. Also, some men may have personal or religious beliefs that do not allow sperm storage. For those who are not candidates for sperm storage in a sperm bank and for those who choose not to bank, discuss other reproductive options such as donor insemination or adoption.

Surgical Management

Surgery is the main treatment for testicular cancer. For Stage 0 or 1 (localized disease), the surgeon performs a radical unilateral **orchiectomy** to remove the affected testicle. Every effort is made to remove the cancerous testis as an intact organ to prevent releasing cancer cells into the surgical site. Depending on the type and stage of the cancer, radical retroperitoneal lymph node dissection (RPLND) may also be done.

Preoperative Care. Like most patients with cancer, the man with testicular cancer is very apprehensive. Offer support, and reinforce the teaching provided by the surgeon. Teach the patient and his family or partner about what to expect after surgery. Depending on the extent of the lymph node dissection and the need for surgical exploration, the surgeon often makes a midline incision. For patients with very early disease, minimally invasive surgery (MIS) using a laparoscope does not require a midline incision. For patients having MIS, teach them that carbon dioxide may be used as part of the surgery. Carbon dioxide can cause chest or shoulder pain from diaphragmatic irritation after the procedure.

Inform the patient and family that traditional open radical retroperitoneal lymph node dissections are long operations. In some cases, the patient may require care in a critical care unit after surgery for close observation.

Operative Procedures. Most patients with seminoma have only one surgery to remove the diseased testicle through the groin (inguinal) for a cure. A frozen section of the tumor is examined to confirm the type and stage of the cancer. A gel-filled silicone prosthesis may be surgically implanted into the scrotum at the time of the orchiectomy or later if the patient desires. Reassure the patient that this procedure does not impair fertility or sexual function. He cosmetically appears to have two testes (reconstructive surgery).

Some men have more advanced disease or tumor types that are more aggressive. These patients require several surgeries to remove both testicles and lymph nodes. Two options are available for the lymph node dissection: a traditional open approach and minimally invasive surgery (MIS) using a laparoscope. To perform the *open* approach, the surgeon removes the retroperitoneal nodes in the iliac and lumbar regions. Because the blood supply and the lymphatic vessels of the testes and kidneys are directly related, an extensive midline

incision from the xiphoid process to the pubis is necessary. Removal of the sympathetic ganglia eliminates peristalsis in the vas deferens and contractions of the seminal vesicles. This disruption results in sterility because the man's ejaculate no longer contains sperm. However, having a normal erection and experiencing orgasm usually are not affected.

The MIS procedure involves using a laparoscope through several small "keyhole" incisions through which the nodes are dissected for examination. This technique shortens the time the patient is in the operating suite, minimizes bleeding, and causes less pain after surgery. The patient has fewer postoperative complications and a shorter hospital stay.

Postoperative Care. Nursing care for the patient after surgery depends on the type of surgical procedure that was performed and the extent of the disease process.

! NURSING SAFETY PRIORITY

Action Alert

Because of the length of the *open* orchiectomy and lymph node dissection approach, manipulation of the abdominal and retroperitoneal viscera, and the loss of lymphatic fluid, observe, assess, and report any complications of this major abdominal surgery (e.g., paralytic ileus) (see Chapter 18). Monitor vital signs (including pain), hydration, and pulmonary function carefully for the first 24 to 48 hours. Ambulate the patient as soon as possible, and teach him how to use the incentive spirometer. Assess the patency of the nasogastric tube (NGT) (if in place) and the urinary catheter. Be sure the patient wears antiembolism stockings or devices, and provide care for surgical incisions and wound drains.

The patient having the *laparoscopic* procedure does not typically have an NGT but may have a urinary catheter in place for 1 to 2 days. The other advantages of the MIS procedure are that patients have less pain and fewer complications than those who had the open surgery. Chapter 17 describes laparoscopic surgery in detail.

? NCLEX EXAMINATION CHALLENGE

Physiological Integrity

A client who had an orchiectomy and laparoscopic radical retroperitoneal lymph node dissection this morning states that he does not understand why he is having shoulder pain. What is the nurse's best response?

- A. "The pain is from the carbon dioxide that was used during surgery."
- B. "You are having pain because of the way you were positioned during surgery."
- C. "What is your level of pain on a scale of 0 to 10, with 10 being the worst pain?"
- D. "Your shoulder should not be hurting because you had a minimally invasive surgery."

Nonsurgical Management

Combination *chemotherapy* may be used as adjuvant therapy for nonseminomatous testicular tumors or as primary treatment when there is evidence of metastatic disease. Many drug regimens are used, including varying combinations of bleomycin, cisplatin, etoposide, and/or vinblastine.

The specific combination of drugs and the frequency, cycling, and duration of treatment vary from patient to patient, depending on the extent of the disease and the protocol being followed. Chapter 24 discusses the general nursing care for the patient receiving chemotherapy.

Patients having chemotherapy are at risk for certain health problems that are associated with these drugs. Examples of these problems include hypertension, hyperlipidemia, coronary artery disease, anemia, and leukemia (Bohenkamp & Yoder, 2009). Teach patients taking these drugs about the long-term effects for which they should be continually and carefully monitored by their health care providers.

After orchiectomy for localized disease, *external beam radiation therapy* (EBRT) is commonly used. The remaining testis is shielded with a lead cup to preserve reproductive function. Even with these precautions, the patient may have a temporary decreased sperm count as a result of radiation scatter. Normally the sperm count returns to the pretreatment level within 24 to 30 months after the radiation treatment is completed. If metastases develop outside the lymphatic system, the man may still be cured with radiation therapy if the area of involvement is limited. If lymphatic involvement is extensive or if the visceral organs are involved, combination chemotherapy is used.

Community-Based Care

The patient is usually hospitalized for multiple days after an *open* radical retroperitoneal lymph node dissection but for just 1 to 2 days for the MIS procedure. This period may need to be extended if he must undergo additional surgery or chemotherapy. Because it may not be known until after the orchiectomy what type of testicular cancer he has or whether he needs additional surgery or treatment, specific discharge planning may need to be delayed until after surgery.

After an *orchiectomy*, unless the patient has a wound complication, he is discharged without a dressing on the inguinal incision. A scrotal support may be needed for several days. He may want to wear a dry dressing to prevent clothing from rubbing on the sutures and causing irritation. Tell him that the sutures will be removed in the physician's office 7 to 10 days after surgery. Patients who also had an *open retroperitoneal lymph node dissection* recover more slowly. They should not lift anything over 15 pounds, should avoid stair climbing, and should not drive a car for several weeks. Be sure that bathroom facilities are on the first floor of the house where he can easily access them.

NURSING SAFETY PRIORITY

Action Alert

For the patient who has undergone testicular surgery, emphasize the importance of scheduling a follow-up visit with the surgeon to examine the incision for healing and complications. Instruct him to notify the surgeon if chills, fever, increasing tenderness or pain around the incision, drainage, or dehiscence of the incision occurs. These manifestations may indicate infection for which antibiotics are needed. Instruct the patient who had an orchiectomy that he will be able to resume most of his usual activities within 1 week after discharge, except for lifting heavy objects (objects weighing more than 15 pounds [6.8 kg]) and stair climbing. Remind him to ask his surgeon when strenuous activities may be resumed.

Inform the patient that he may make arrangements to have a silicone prosthesis inserted into the scrotum if one was not inserted during the orchiectomy. Explain the importance of performing monthly testicular self-examination (TSE) on the remaining testis and scheduling follow-up examinations with the physician. The patient who has had testicular cancer

should schedule tests for urinary and serum levels of tumor markers and CT or MRI studies as part of his routine follow-up for at least 3 years.

Depending on the pathologic findings and the stage of the cancer, the patient may need further treatment. This information may not be known at the time of discharge. If it is known that the patient needs further surgery, he and his family need information about the future surgery. If it is known that he must undergo radiation therapy or chemotherapy, he needs education about these treatments as soon as possible.

The man who has testicular cancer needs emotional support. If permanent sterility occurs and sperm storage has not been feasible, he may desire counseling about other reproductive options. Refer the patient to agencies or support groups, such as the American Fertility Society (www.theafa.org) or RESOLVE: The National Infertility Association (www.resolve.org) (organizations for infertile couples).

OTHER PROBLEMS AFFECTING THE TESTES AND ADJACENT STRUCTURES

Problems that develop inside the scrotum usually occur as a mass or as scrotal edema. Some problems produce pain, but others do not. Fig. 75-5 shows some of the most common conditions found in men, including hydrocele, spermatocele, varicocele, and scrotal torsion.

HYDROCELE

A hydrocele is a cystic mass, usually filled with straw-colored fluid that forms around the testis (see Fig. 75-5). It results from impaired lymphatic drainage of the scrotum causing a swelling of the tissue surrounding the testis. Unless the swelling becomes large and uncomfortable or begins to impair blood flow to the testis, no treatment is necessary. Hydroceles are usually painless. It is important that the cause of the hydrocele is investigated to rule out a serious condition. The cause may be determined by examination and ultrasound. A small hydrocele may go untreated with no further problems. However, a hydrocele may become very large, which makes clothing uncomfortable and may be cosmetically unacceptable.

A hydrocele may be drained via a needle and syringe, or it may be removed surgically in an ambulatory care setting. The patient may or may not have a drain at the incision site. Teach the man that if an incision drain is present, some serosanguineous drainage may be present for the first 24 to 48 hours after surgery. Explain the importance of wearing a scrotal support (jock strap). This device keeps the dressing in place and the scrotum elevated, which helps prevent edema.

The degree of pain experienced after this surgery varies. Assess and observe the patient for pain every 2 to 3 hours immediately after surgery. Moderate incision pain is expected for the first 24 hours after surgery and should markedly decrease within 1 or 2 days. If the pain does not resolve within this time, assess for wound complications, such as infection or bleeding.

Instruct the man to schedule a follow-up visit with the surgeon to have the wound evaluated for healing. Stress the importance of continuing to wear a scrotal support to promote drainage and comfort. The scrotum can remain swollen from residual inflammation and edema for as long as several weeks. Remind the patient to stay off his feet for

FIG. 75-5 Common problems affecting the testes and adjacent structures.

several days and to limit physical activity for a week. Reassure him that this swelling is normal and eventually subsides.

SPERMATOCELE

A spermatocele is a sperm-containing cyst that develops on the epididymis alongside the testicle (see Fig. 75-5). Trauma, infection, congenital abnormalities, or often for no identifiable reason results in the widening of a portion of the epididymis, creating a small cavity where sperm collects.

Normally, spermatoceles are small and asymptomatic and no interventions are needed. If they become large enough to cause discomfort, a spermatocelectomy is performed. In this simple procedure, the spermatocele is removed through a small scrotal incision. Routinely, no incision drain is used because drainage and swelling are minimal. A few patients have recurrence.

VARICOCELE

A varicocele is a cluster of dilated veins behind and above the testis (see Fig. 75-5). Varicosity of the testicles may result from the increased fluid secondary to damaged or incompetent valves in the testicular veins. The diagnosis is made by scrotal palpation, particularly when the patient performs a Valsalva maneuver, creating additional pressure in the varicose veins. The scrotum feels “wormlike” when palpated. If the varicocele is very small and cannot be palpated, thermography, which detects pockets of heat, or a Doppler, which magnifies the sound of the blood flowing through the veins, is used.

Varicoceles can be either unilateral or bilateral, but most are unilateral. They occur most often on the left side of the scrotum. In many cases, they are asymptomatic and no treatment is required. In a few men, varicoceles are painful and must be removed surgically.

Varicoceles can also cause infertility. It is thought that they increase scrotal temperature from the venous stasis near the testis, altering spermatogenesis. Surgical correction may

resolve the infertility. As an alternative, an interventional radiology procedure may be done to embolize the vein that drains the varicocele.

A **varicocelectomy** (surgical removal of the varicocele) is usually performed through an inguinal incision, in which the spermatic veins are ligated in the cord. It can also be performed through an incision near the superior iliac spine, in which the spermatic veins are ligated in the retroperitoneal space. A varicocelectomy may be done on an ambulatory care basis.

Before surgery, explain to the patient that persistent venous congestion of the scrotum is common after this type of surgery because of the changed circulation in the area. To promote drainage of the scrotum, place a rolled towel under the scrotum while he is in bed. Ice may be applied to the scrotum if needed. Any intervention that facilitates drainage and decreases swelling from the area promotes relief. Instruct the patient about the importance of wearing a scrotal support while ambulating. Usually he can resume normal activities, including sexual activities, within a week.

At discharge, instruct the patient to make a follow-up appointment with the surgeon to have the sutures removed. Remind him to notify the surgeon of any increasing discomfort at the incision site or in the scrotum, which might indicate an infection. Increasing scrotal discomfort can mean that the circulation to the testis has been impaired. Testicular atrophy, a rare complication of a varicocelectomy, may occur if the blood supply to the testis becomes insufficient.

CANCER OF THE PENIS

Pathophysiology

Cancer of the penis is rare among men in the United States. Most penile cancers are epidermoid (squamous) carcinomas developing from the squamous cells. These tumors tend to grow slowly and can develop anywhere on the penis but occur

most commonly on the foreskin or the glans. When the cancer is confined to the skin of the penis, it is called *carcinoma in situ (CIS)*. Other types of penile cancers include melanomas, basal cell cancers, and sarcomas.

Circumcision (the surgical removal of the prepuce from the penis) in infancy almost eliminates the possibility of penile cancer in that chronic irritation and inflammation of the glans penis predispose uncircumcised men to penile cancer. Because of the ongoing controversy about neonatal circumcision, teach men and new mothers of boys that strict personal hygiene is an important preventive measure against penile cancer.

PATIENT-CENTERED COLLABORATIVE CARE

Penile cancer usually occurs as a painless, wartlike growth or ulcer on the glans under the **prepuce** (foreskin) and may be mistaken for a venereal wart. It may also appear as a reddened lesion with plaque.

Small lesions involving only the skin may be controlled by excisional biopsy. When the lesion is not curable by excisional biopsy or radiation therapy, a **penectomy** (partial or total removal of the penis) may be required. When the lesion is limited to the glans, a partial penectomy is performed. The distal portion of the corpus cavernosum and the corpus spongiosum is amputated. The urethra is connected to the skin, and a dressing is applied. A retention catheter is in place for 3 to 5 days after surgery until the edema surrounding the urethra subsides. Assess the dressing for drainage, which should be minimal. Check the urinary catheter for patency every 4 hours for the first 24 hours.

A total penectomy is required when the lesion has penetrated the shaft of the penis or when the tumor has recurred after a partial penectomy or radiation therapy. An incision is made from the pubic bone, which encircles the penis and extends into the perineum. The bases of both corpora cavernosa are exposed and excised, and the penis is amputated. An incision drain is placed in the wound before it is sutured. Patients who undergo a total penectomy also have a perineal urethrotomy (connecting the urethra to the skin in the perineum) for urinary drainage.

After a total penectomy, observe the incision dressing every 2 to 4 hours during the first 24 hours. A moderate amount of serosanguineous drainage from the incision drains is expected.

Be aware that regardless of how accepting the patient may appear before surgery, he may experience severe emotional problems after surgery. After a partial penectomy, he must adjust to considerable changes in body image and sexuality. Encourage him to verbalize his feelings about the loss of his penis. After a total penectomy, the patient can no longer have penile-vaginal or penile-anal intercourse and cannot urinate in a standing position. It is difficult for most men to accept the possibility that they might die because of a lesion on the penis, especially because they rarely experience any systemic cancer symptoms and are otherwise healthy. Help the patient realize that removal of his penis may save his life. Be aware of the possibility of suicide attempts because his penis may be more important to him than his life. The nurse may be the one to detect the need for professional psychological

FIG. 75-6 An uncircumcised penis.

assistance for the patient or his partner. Early interventions can make a tremendous difference in the patient's or partner's well-being.

PHIMOSIS AND PARAPHIMOSIS

In *phimosis*, the prepuce is constricted so that it cannot be retracted over the glans. The prepuce remains down, around the tip of the penis. Teach uncircumcised men about the importance of cleaning the prepuce (Fig. 75-6).

In *paraphimosis*, the prepuce has not been returned to its normal position after being retracted and forms a constricting band around the glans. This constricts lymph drainage, causing the penis to swell. Blood flow becomes impeded, and tissue death can occur. *This problem is an emergency requiring immediate treatment. Uncircumcised males are at risk.* Causes include infection, not returning the foreskin to the original position, poor hygiene, vigorous sexual intercourse, and penile piercing. *When caring for a man who is not circumcised, be sure to replace the foreskin over the penis after bathing or catheterizing him to prevent this paraphimosis!*

Phimosis is corrected by **circumcision** (surgical removal of the prepuce or foreskin). This procedure also may be performed for other medical reasons or for aesthetic reasons. Circumcision in the adult male is usually performed in a same-day surgical setting. If the patient has a dressing, instruct him to soak in a warm bath that evening to allow the dressing to loosen. If the dressing falls off before the next day, caution him to not replace it. Explain that the sutures will be absorbed and need not be removed. No residual or side effects result from this surgery, and the patient should be able to resume normal activities within 1 week. Sexual intercourse may be resumed after 1 to 2 weeks when pain has subsided. Advise the man to notify his physician if he has any wound complications, such as swelling at the incision area or drainage, and to schedule a postoperative office visit.

PRIAPISM

Priapism is an uncontrolled, long-maintained erection without sexual desire, which causes the penis to become large, hard, and painful. It affects the two corpora cavernosa. The corpus spongiosum and glans penis are not affected.

Priapism can occur from neural, vascular, or pharmacologic causes, including:

- Thrombosis of the veins of the corpora cavernosa (usually resulting from trauma)
- Leukemia
- Sickle cell disease
- Diabetes mellitus
- Malignancies

Sickle cell disease causes priapism through the collection of erythrocytes within the corporal bodies. Leukemia may cause priapism because the increased number of white blood cells (WBCs) permits persistent engorgement of the corporal bodies. Cancer may also infiltrate the corporal bodies causing persistent engorgement. Priapism can also result from an abnormal neurogenic reflex, psychotropic drugs, antidepressants, antihypertensive drugs, and drugs used to treat erectile dysfunction. Other risk factors include recreational drugs (cocaine, ecstasy, marijuana), overdose of injectable drugs for erectile dysfunction, and prolonged sexual activity.

Priapism is a urologic emergency because the circulation to the penis may be compromised and the patient may not be able to void with an erect penis. The desired outcome for intervention is to improve the venous drainage of the corpora cavernosa. Conservative measures involve prostatic massage, sedation, ice packs, and bedrest. Meperidine (Demerol) is usually given immediately because of its hypotensive effect. Urinary catheterization is required if the man cannot void.

If conservative therapy is unsuccessful, treatment may proceed to aspiration of the corpora cavernosa with a large-bore needle or surgical intervention. The priapism should be resolved within the first 24 to 30 hours to prevent penile ischemia, gangrene, fibrosis, and erectile dysfunction. If a cause is identified, treatment is directed toward that underlying cause.

When caring for the patient with priapism, be sensitive to his emotional needs. He may be uncomfortable and in crisis but at the same time embarrassed by his erection and loss of control. Reassure the patient that it is understood that he is not in control of his erection, and provide him with privacy.

PROSTATITIS

Pathophysiology

Prostatitis is an inflammation of the prostate gland. The four types of prostatitis are acute bacterial (ABP), chronic bacterial (CBP), nonbacterial (NBP)/chronic pelvic pain syndrome (CPPS), and asymptomatic inflammatory prostatitis. Duration of symptoms, presence or absence of WBCs in the urine, and urinary culture results determine the classification.

Bacterial prostatitis often occurs with urethritis or an infection of the lower urinary tract. Organisms may reach the prostate via the bloodstream or the urethra. The most common organisms are *Escherichia coli*, *Enterobacter*, *Proteus*, and group D streptococci. Acute bacterial prostatitis may be manifested by fever, chills, **dysuria** (painful urination), urethral discharge, and a boggy, tender prostate. Gentle palpation of the prostate usually results in a urethral discharge, which has WBCs in the prostatic secretions.

Chronic bacterial prostatitis generally occurs in older men and has a less dramatic presentation than acute bacterial prostatitis and without the systemic manifestations. The patient reports experiencing hesitancy, urgency, dysuria,

difficulty initiating and terminating the flow of urine, and decreased strength and volume of urine. Also, there may be discomfort in the perineum, scrotum, and penis.

Prostatitis can occur after a viral illness or may be associated with sexually transmitted diseases (STDs), especially in young males. Other causes may be autoimmune disorders, neuromuscular etiologies, allergy-mediated reactions, and psychosexual problems. In many instances, an exact cause of the perineal discomfort cannot be found. The patient reports mild urgency and dysuria. Rectal, perineal, and ejaculatory pain may be present. Decreased libido (sexual desire) may also be present.

Prostatodynia (pelvic floor pain) is a related condition in which manifestations of prostatitis are present but there is no inflammation of the prostate and the urine culture is negative. Also, the patient has low back pain with unilateral testicular pain, narrowed urinary stream with diminished force, and post-void dribbling.

PATIENT-CENTERED COLLABORATIVE CARE

The patient with chronic prostatitis usually reports backache, perineal pain, mild dysuria, and urinary frequency. Hematuria may be present. The prostate may feel irregularly enlarged, firm, and slightly tender when palpated. The patient often has an elevated serum WBC count and prostate-specific antigen (PSA) level.

Complications of prostatitis are **epididymitis** (inflammation of the epididymis) and **cystitis** (inflammation of the bladder). A rare complication is a prostatic abscess. The patient with either acute or chronic bacterial prostatitis is likely to develop urinary tract infections. Sexual functioning may be reduced because of discomfort.

Early diagnosis and treatment of prostatitis with antimicrobials are important. Treatment may last from weeks to many months because there is poor penetration of antibiotics into prostatic tissue. Acute bacterial prostatitis may require hospitalization with aggressive IV antibiotics.

Emphasize the importance of comfort measures, such as sitz baths, muscle relaxants, and NSAIDs. Stool softeners are prescribed to prevent straining and rectal irritation of the prostate during a bowel movement. Alpha blockers such as tamsulosin (Flomax) may be given to promote voiding. Teach patients to avoid alcohol, coffee, tea, and spicy foods that irritate symptoms. Instruct them to avoid over-the-counter cold preparations containing decongestants or antihistamines that may cause urinary retention.

Teach the patient with chronic prostatitis about the long-term nature of the problem. Because prostatitis can cause other urinary tract infections, explain the importance of long-term antibiotic therapy and increasing fluid intake. Remind him to take the prescribed antibiotics on schedule. Because sulfamethoxazole-trimethoprim (Bactrim, Septra) diffuses into the prostatic fluid, it is often the antibiotic of choice. Before drug administration, be sure that the patient does not have any allergy to sulfa drugs.

Teach the patient about activities that drain the prostate (sexual intercourse, masturbation), which may help in the management of chronic prostatitis. Inform him that prostatitis is not infectious or contagious.

EPIDIDYMITIS

Pathophysiology

Epididymitis is an inflammation of the epididymis and may be a result of an infection or noninfectious source such as trauma. Bacterial infection is the most common cause. The infection may spread from other structures such as the prostate, bladder, or urethra. It can be a complication of an STD, such as gonorrhea or chlamydia. Although not common, epididymitis can also be a complication of long-term use of an indwelling urinary catheter, prostatic surgery, or a cystoscopic examination.

Organisms such as *Staphylococcus* and *E. coli* commonly cause epididymitis. Some men have *Chlamydia trachomatis*, which is transmitted sexually (see [Chapter 76](#)). The infective organism passes upward through the urethra and the ejaculatory duct and then along the vas deferens to the epididymis.

The man with epididymitis usually reports pain along the inguinal canal and along the vas deferens, followed by pain and swelling in the scrotum and the groin. If untreated, the epididymis becomes swollen and painful and fever may be present. Pyuria and bacteriuria may develop with resultant chills and fever. An abscess may form, requiring an **orchiectomy** (removal of one or both testes).

PATIENT-CENTERED COLLABORATIVE CARE

Instruct the patient with epididymitis to remain in bed with his scrotum elevated to prevent traction on the spermatic cord, to facilitate venous drainage, and to relieve pain. The man should wear a scrotal support when ambulating. A smear or culture of the urine or prostate secretions may be obtained to identify the causative organism. Antibiotics appropriate to the specific organism can then be prescribed. These antibiotics are taken until all acute manifestations are gone. If the epididymitis is chlamydial or gonorrheal in origin, the patient's sexual partners are also treated with antibiotics. NSAIDs such as ibuprofen or naproxen

(Naprosyn) may be used to decrease inflammation and promote comfort.

The patient may find other comfort measures effective, such as applying cold compresses or ice to the scrotum intermittently and taking sitz baths. Advise him to avoid lifting, straining, or sexual activity until the infection is under control (which may take as long as 4 weeks).

In men with epididymitis, a testicular tumor must always be suspected, especially if the condition does not resolve in a week or two. Ultrasound study is often done to rule out an abscess or tumor. Patients with recurrent or chronic painful conditions may require an **epididymectomy** (excision of the epididymis from the testicle).

ORCHITIS

Orchitis is an acute testicular inflammation resulting from trauma or infection. The infection may be caused by the direct spread of bacteria through the urethra or by an infection elsewhere in the body, such as pneumonia, tuberculosis, gonorrhea, syphilis, or mumps. Usually both the testes and the epididymides are involved (epididymo-orchitis). Risk factors for orchitis include recurrent urinary tract infections, recurrent STDs, congenital abnormalities of the urogenital tract, instrumentation, and chronic indwelling urethral urinary catheter.

Orchitis may be unilateral or bilateral. If it is bilateral, the patient is at increased risk for sterility because of the testicular atrophy and fibrosis that occur during healing.

The manifestations of orchitis are the same as those of epididymitis and include scrotal pain, edema, reports of heavy feelings in the involved testicle(s), dysuria, pain on ejaculation, blood in the semen, and discharge from the penis. In addition, the patient may experience nausea and vomiting and pain radiating to the inguinal canal.

The treatment of orchitis is the same as for epididymitis and includes:

- Bedrest with scrotal elevation
- Application of ice
- Administration of analgesics and antibiotics

NURSING CONCEPT REVIEW

What might you NOTICE if the patient is experiencing impaired sexuality as a result of male reproductive problems?

- Lump or swelling in prostate or scrotum
- Report of pain in scrotum or during ejaculation
- Report of difficulty voiding (e.g., starting urine stream)
- Hematuria
- Report of dribbling of urine (incontinence)
- Report of inability to have a penile erection
- Report of decreased libido

What should you INTERPRET and how should you RESPOND to a patient experiencing impaired sexuality as a result of male reproductive problems?

Perform and interpret physical assessment, including:

- Conducting a complete pain assessment
- Inspecting and palpating bladder for distention
- Inspecting and palpating scrotum for swelling or masses
- Palpating lymph nodes for swelling, especially in the inguinal areas
- Sending urine sample for urinalysis and culture
- Checking most recent laboratory values for PSA, CBC, and serum tumor markers

Respond by:

- Catheterizing patient if retaining urine
- Providing pain relief measures, such as ice or medication as prescribed

NURSING CONCEPT REVIEW—cont'd

- Elevating scrotum if swollen
- Arranging for consultation with sex or intimacy therapist, if patient desires

On what should you REFLECT?

- Evaluate patient for need for indwelling urinary catheter.
- Evaluate effectiveness of actions to control pain and swelling.
- Think about what additional resources the patient will need to cope with his problem.

GET READY FOR THE NCLEX® EXAMINATION!

KEY POINTS

Review these Key Points for each NCLEX Examination Client Needs Category.

Safe and Effective Care Environment

- Teach patients with prostate cancer about American Cancer Society's Man to Man program and the American Foundation for Urologic Disease's Us TOO program to help men and their partners cope with prostate cancer.
- Have patients report signs of infection when caring for a urinary catheter in the home.

Health Promotion and Maintenance

- Teach men at risk for prostate cancer to follow the current American Cancer Society's screening and early detection guidelines.
- Teach men how to perform testicular self-examination as described in [Chart 75-4](#).
- Teach uncircumcised men the importance of keeping the penis clean to prevent penile cancer.

Psychosocial Integrity

- Because most patients with testicular cancer are young and middle-aged adults, assess their reaction to the possible loss of reproductive ability.
- Because of the high incidence of erectile dysfunction after radical prostatectomy, assess the patient's adjustment to these changes in body function.
- Assess the patient's anxiety before prostate surgery, and allow him to express feelings of fear or grief.

Physiological Integrity

- Perform a focused physical assessment for patients reporting lumps or swelling in their genital area; inspect and palpate bladder and scrotum.
- Observe for and report complications after radical prostatectomy.

- Observe for and report bloody urine with clots after TURP; irrigate the bladder per agency or surgeon protocol.
- Maintain traction on the urinary catheter after a TURP.
- Teach patients about drug therapies (5-ARIs and alpha blocking agents) used to treat BPH, including side effects.
- Teach patients to avoid any drugs that can cause urinary retention, especially anticholinergics, antihistamines, and decongestants if BPH is present.
- Remind patients wanting to use complementary and alternative therapies to check with their health care providers before using them.
- Eating a well-balanced diet with plenty of fish and fruits and vegetables may help prevent prostate cancer.
- Reinforce the man's option for managing prostate cancer; some procedures and drugs cause erectile dysfunction and incontinence either temporarily or permanently.
- Use the information listed in [Chart 75-3](#) to teach patients urinary catheter care after prostate cancer surgery.
- Teach patients about not lifting more than 15 lb (6.8 kg) after prostate surgery.
- Options for erectile dysfunction (ED) include drug therapy (most common), vacuum assist devices, penile injections, transurethral suppositories, or penile implants.
- Be aware that African-American middle-aged men are the most at risk for prostate cancer; Euro-American young men are the most at risk for testicular cancer.
- Teach patients to report symptoms of radiation cystitis or proctitis to their health care provider as soon as possible; these complications resolve in 4 to 6 weeks after the end of radiation therapy.
- Teach patients and their partners about hormonal therapy used to manage prostate cancer: LH-RH agonists and anti-androgen drugs.
- Be aware that sexually transmitted diseases (STDs) are a major cause of male reproductive system infections.

Care of Patients with Sexually Transmitted Disease

Concept Map Creator

Key Points

Self-Assessment Questions for the NCLEX® Examination

LEARNING OUTCOMES

Safe and Effective Care Environment

1. Maintain patient confidentiality and privacy related to sexually transmitted diseases (STDs).
2. Educate patients with STDs and their sexual partners on self-care measures.

Health Promotion and Maintenance

3. Describe the role of expedited partner treatment in reducing STD recurrence.
4. Develop a health teaching plan for young adults and other at-risk people about risk factors, prevention, and treatment for STDs.

Psychosocial Integrity

5. Assess patients' and their partners' responses to a diagnosis of STD.

6. Explain the need to respect patients' personal values and beliefs regarding sexual practices.

Physiological Integrity

7. Compare the stages of syphilis.
8. Identify the role of drug therapy in managing patients with STDs.
9. Develop a health teaching plan for patients on how to self-manage their STD, including antibiotic therapy.
10. Describe the assessment findings that are typical in patients with STDs.
11. Develop a collaborative plan of care for a patient with pelvic inflammatory disease (PID).
12. Identify three sexually transmitted vaginal infections.

OVERVIEW

Sexually transmitted diseases (STDs) are caused by infectious organisms that have been passed from one person to another through intimate contact, usually oral, vaginal, or anal intercourse. Some organisms that cause these diseases are transmitted only through sexual contact. Other organisms are transmitted also by parenteral exposure to infected blood, fecal-oral transmission, intrauterine transmission to the fetus, and perinatal transmission from mother to neonate (Table 76-1). *Sexually transmitted infections (STIs)* is another term that has been used to describe the same group of health problems. This terminology was intended to focus on the management of these infections and to decrease the social

stigma of labeling them as diseases. Though used in the literature, *STI* is the less common terminology. *STD continues to be the most acceptable term used by the Centers for Disease Control and Prevention (CDC).*

In spite of improved diagnostic techniques, increased knowledge about organisms that can be sexually transmitted, and changes in sexual attitudes and practices, the number of cases of STDs continues to increase. *Sexual issues are often sensitive, personal, and controversial, and nurses must respect the patients' lifestyle. Providing confidentiality is essential for patients to receive correct information, make informed decisions, and obtain appropriate care.*

The prevalence of STDs is a major health concern worldwide. Populations at greatest risk for acquiring STDs are

TABLE 76-1 SEXUALLY TRANSMITTED DISEASES

- Human immune deficiency virus infection - Chancroid - Syphilis - Lymphogranuloma venereum - Genital herpes simplex virus infection - Genital warts - Gonococcal infection - Chlamydia infection - Nongonococcal urethritis - Mucopurulent cervicitis - Epididymitis	- Pelvic inflammatory disease - Sexually transmitted enteritis - Sexually transmitted proctitis - Trichomoniasis - Candidal infection - Bacterial vaginosis - Viral hepatitis - Cytomegalovirus infection - Ectoparasitic infection: - Pediculosis pubis - Scabies

pregnant women, adolescents, and men who have sex with men (MSM). External factors such as an increasing population, cultural factors (e.g., earlier first intercourse), political and economic policies, and international travel and migration affect the prevalence of STDs. It is also affected by changing human physiology patterns such as earlier menarche, comorbidities leading to immunosuppression such as from human immune deficiency virus (HIV), or treatments for cancer or organ transplantation. Access to care plays a major role in the risk for acquiring an STD.

WOMEN'S HEALTH CONSIDERATIONS

Because of the very vascular mucous membranes of the vagina, women are more easily infected with STDs than are men and are at greater risk for health problems caused by STDs. Young women who are sexually active with men have an increased risk for contracting an STD for several reasons including increased rates of sexual activity that may be unprotected and exposure of cervical basal epithelium cells to infections. Lesbian women have a decreased risk for STDs, although many have or have had sex with men.

Some young women may also be at high risk because they:

- Lack knowledge about the risk for disease
- Believe that they are not vulnerable to disease
- Mistakenly believe that oral contraceptives; contraceptive patches, sponges, and foams; and intrauterine devices also protect them from STDs
- Consume large amounts of alcohol, which promotes risky sexual behavior

Postmenopausal women also may be at risk for STDs because many perceive that pregnancy is no longer likely and thus do not use barrier protection. Mucosal tears from vaginal atrophy in postmenopausal women may also place them at risk.

Women have more asymptomatic infections that may delay diagnosis and treatment. Many STDs reside in the cervical os and cause little change in vaginal discharge or vulvar tissue. This delay increases the likelihood of complications from STDs, including ascending infections that may cause reproductive organ damage and illness. Embarrassment, denial, or fear about STDs may further delay treatment, increasing the potential for serious complications.

STDs cause complications that can contribute to severe physical and emotional suffering, including infertility, ectopic pregnancy, cancer, and death. Some of the most common complications caused by sexually transmitted organisms are listed in Table 76-2.

TABLE 76-2 COMPLICATIONS CAUSED BY SEXUALLY TRANSMITTED ORGANISMS

COMPLICATION	CAUSATIVE ORGANISMS
Salpingitis, infertility, and ectopic pregnancy	<i>Neisseria gonorrhoeae</i> <i>Chlamydia trachomatis</i> <i>Mycoplasma hominis</i> <i>Ureaplasma urealyticum</i>
Reproductive loss (abortion/miscarriage)	<i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus <i>M. hominis</i> <i>U. urealyticum</i> <i>Treponema pallidum</i>
Puerperal infection	<i>N. gonorrhoeae</i> <i>C. trachomatis</i>
Perinatal infection	Hepatitis B virus Human immune deficiency virus Human papilloma virus <i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus <i>T. pallidum</i> Cytomegalovirus Group B streptococcus
Cancer of genital area	Human papilloma virus
Male urethritis	<i>M. hominis</i> Herpes simplex virus <i>N. gonorrhoeae</i> <i>C. trachomatis</i> <i>U. urealyticum</i>
Vulvovaginitis	Herpes simplex virus <i>Trichomonas vaginalis</i> Bacterial vaginosis <i>Candida albicans</i>
Cervicitis	<i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus
Proctitis	<i>N. gonorrhoeae</i> <i>C. trachomatis</i> Herpes simplex virus <i>Campylobacter jejuni</i> <i>Shigella species</i> <i>Entamoeba histolytica</i>
Hepatitis	<i>T. pallidum</i> Hepatitis A, hepatitis B, and hepatitis C viruses
Dermatitis	<i>Sarcoptes scabiei</i> <i>Phthirus pubis</i>
Genital ulceration or warts	<i>C. trachomatis</i> Herpes simplex virus Human papilloma virus <i>T. pallidum</i> <i>Haemophilus ducreyi</i> <i>Calymmatobacterium granulomatis</i>

Chlamydia infection, gonorrhea, syphilis, chancroid, human immune deficiency virus (HIV) infection, and acquired immune deficiency syndrome (AIDS) are reportable to local health authorities in every state (Centers for Disease Control and Prevention [CDC], 2008). Other STDs such as genital herpes (GH) may or may not be reported, depending on local legal requirements. Positive results can be reported

by clinicians and laboratories. Reports are kept strictly confidential.

Nurses in a variety of settings are responsible for identifying people at risk for STDs, caring for patients with diagnosed STDs, and preventing further cases through education and case finding. Nurses in secondary and tertiary care settings, such as acute care hospitals, have a responsibility to recognize patients who are at risk for or who have STDs, possibly while being treated for another unrelated health problem.

The CDC provides regularly updated guidelines for treatment of STDs. These best practice guidelines provide information, treatment standards, and counseling advice to help decrease the spread of these diseases (CDC, 2010a).

INFECTIONS ASSOCIATED WITH ULCERS

SYPHILIS

Pathophysiology

Syphilis is a complex sexually transmitted disease (STD) that can become systemic and cause serious complications, including death. The causative organism is a spirochete called *Treponema pallidum*. Although the organism can be seen only with a darkfield microscope, several serologic tests may be used to screen for the presence of syphilis antibody. *T. pallidum* is damaged by dry air or any known disinfectant. The organisms die within hours at temperatures of 105.8° to 107.6° F (41° to 42° C) and are not airborne. *The infection is usually transmitted by sexual contact and blood exposure, but transmission can occur through close body contact such as kissing.*

Syphilis progresses through four stages: primary, secondary, latent, and tertiary. The appearance of an ulcer called a **chancre** is the first sign of *primary* syphilis. It develops at the site of entry (inoculation) of the organism from 10 to 90 days after exposure (3 weeks is average). Chancres may be found on any area of the skin or mucous membranes but occur most often on the genitalia, lips, nipples, and hands and in the mouth, anus, and rectum.

During this highly infectious stage, the chancre begins as a small papule. Within 3 to 7 days, it breaks down into its typical appearance: a painless, indurated (hard), smooth, weeping lesion. Regional lymph nodes enlarge, feel firm, and are not painful. Without treatment, the chancre usually disappears within 6 weeks. However, the organism spreads throughout the body and the patient is still infectious.

Secondary syphilis develops 6 weeks to 6 months after the onset of primary syphilis. During this stage, syphilis is a systemic disease because the spirochetes circulate throughout the bloodstream. Common manifestations include:

- Malaise
- Low-grade fever
- Headache
- Muscular aches and pains
- Sore throat
- Generalized rash

These symptoms are often mistaken for those of influenza. The rash, the most commonly presenting symptom, usually involves the palms and soles of the feet. Although it has no typical appearance, the rash tends to change from papules to squamous papules to pustules. Other skin lesions include psoriasis-like rashes (Fig. 76-1), wartlike lesions (condylomata lata), and mucous patches. *These lesions are highly*

FIG. 76-1 Palmar and plantar secondary syphilis.

contagious and should not be touched without gloves. The rash subsides without treatment in 4 to 12 weeks.

After the second stage of syphilis, there is a period of latency. *Early latent* syphilis occurs during the first year after infection, and infectious lesions can recur. *Late latent* syphilis is a disease of more than 1 year's duration after infection. This stage is not infectious except to the fetus of a pregnant woman. Patients with latent syphilis may or may not have reactive serologic test (e.g., Venereal Disease Research Laboratory [VDRL]) findings.

Tertiary, or late, syphilis occurs after a highly variable period, from 4 to 20 years. This stage develops in untreated cases and can mimic other conditions because any organ system can be affected. Manifestations of late syphilis include:

- Benign lesions (gummas) of the skin, mucous membranes, and bones
- Cardiovascular syphilis, usually in the form of aortic valvular disease and aortic aneurysms
- Neurosyphilis, causing central nervous system problems (e.g., meningitis, hearing loss, generalized paresis [weakness])

Because of strong U.S. public health efforts between 1990 and 1996, there was a 90% decrease in syphilis cases to an all-time low in 2000. Since 2001, there has been a steady increase in cases of primary and secondary syphilis with the majority among men having sex with men (MSM) (CDC, 2009).

CULTURAL AWARENESS

African Americans have an 8 times greater rate of acquiring syphilis than whites. Compared with whites, the 2008 rate for Hispanics was 2 times higher (CDC, 2009). The reason for these differences is unclear, but lack of access to health care may be a factor.

Health Promotion and Maintenance

One of the *Healthy People 2020* objectives is to completely eliminate syphilis in the United States (U.S. Department of Health and Human Services [USDHHS], 2010) (Table 76-3). The most important tool for prevention of sexually transmitted diseases (STDs), including syphilis, is education. All people, regardless of age, gender, ethnicity, socioeconomic

TABLE 76-3 MEETING HEALTHY PEOPLE 2020 OBJECTIVES AND TARGETS FOR IMPROVEMENT: SEXUALLY TRANSMITTED DISEASES

- Reduce the proportion of adolescents and young adults with Chlamydia trachomatis infections (by 10%).
- Reduce the proportion of females ages 15 to 44 years who have ever required treatment for pelvic inflammatory disease (by 10%).
- Reduce gonorrhea rates (by 10%).
- Reduce sustained domestic transmission of primary and secondary syphilis (by 10%).
- Reduce the proportion of females with human papilloma virus (HPV) infection (no specific target).
- Reduce the proportion of young adults with genital herpes due to herpes simplex type 2 (by 10%).

status, education, or sexual orientation, are susceptible to these diseases. STDs are largely preventable through safer sex practices. *Do not assume that a person is not sexually active because of his or her age, education, marital status, profession, or religion.* Discuss prevention methods, including safe sex, with all patients who are or may become sexually active.

Safe sex practices are those that reduce the risk for nonintact skin or mucous membranes coming in contact with infected body fluids and blood. These practices include using:

- A latex or polyurethane condom for genital and anal intercourse
- A condom or latex barrier (dental dam) over the genitals or anus during oral-genital or oral-anal sexual contact
- Gloves for finger or hand contact with the vagina or rectum

Abstinence, mutual monogamy, and decreasing the number of sexual partners also decrease the risk for acquiring an STD.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Assessment of the patient who has manifestations of syphilis begins with a history to gather information about any ulcers or rash. Take a sexual history and conduct a risk assessment to include whether previous testing or treatment for syphilis or other STDs has ever been done (Chart 76-1). Ask about allergic reactions to drugs, especially penicillin. A woman may report inguinal lymph node enlargement resulting from a chancre in the vagina or cervix that is not easily visible to her. She may state a history of sexual contact with a male partner who had an ulcer that she noticed during the encounter. Men usually discover the chancre on the penis or scrotum.

Conduct a physical examination, including inspection and palpation, to identify manifestations of syphilis. *Wear gloves while palpating any lesions because of the highly contagious treponemes that are present.* Observe for and document rashes of any type because of the variable presentation of secondary syphilis.

After the physical examination, the health care provider obtains a *specimen of the chancre* for examination under a darkfield microscope. Diagnosis of primary or secondary syphilis is confirmed if *T. pallidum* is present.

CHART 76-1 FOCUSED ASSESSMENT

The Patient with a Sexually Transmitted Disease

Assess history of present illness:

- Chief concern
- Symptoms by quality and quantity, precipitating and palliative factors
- Any treatments taken (self-prescribed or over-the-counter products)

Assess past medical history:

- Major health problems—including any history of STDs/PID or immunosuppression
- Surgeries—obstetric and gynecologic, circumcision

Assess current health status:

- Menstrual history for irregularities
- Sexual history:
 - Type and frequency of sexual activity
 - Number of sexual contacts/partners
 - Sexual orientation
- Contraceptive history
- Medications
- Allergies
- Lifestyle risks—drugs, alcohol, tobacco

Assess preventive health care practices:

- Papanicolaou (Pap) tests
- Regular STD screening
- Use of barrier contraceptives to prevent STDs and pregnancy

Assess physical examination findings:

- Vital signs
- Oropharyngeal findings
- Abdominal findings
- Genital or pelvic findings
- Anorectal findings

Assess laboratory data:

- Urinalysis
- Hematology
- ESR or CRP if PID is being considered
- Cervical, urethral, oral, rectal specimens
- Lesion samples for microbiology and virology
- Pregnancy testing

CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; PID, pelvic inflammatory disease; STDs, sexually transmitted diseases.

Blood tests are also used to diagnose syphilis. The usual screening and/or diagnostic nontreponemal tests are the *Venereal Disease Research Laboratory (VDRL)* serum test and the more sensitive *rapid plasma reagin (RPR)*. These tests are based on an antibody-antigen reaction that determines the presence and amount of antibodies produced by the body in response to an infection by *T. pallidum*. They become reactive 2 to 6 weeks after infection. VDRL titers are also used to monitor treatment effectiveness. The antibodies are not specific to *T. pallidum*, and false-positive reactions often occur from such conditions as viral infections, hepatitis, and systemic lupus erythematosus (SLE) (Pagana & Pagana, 2010).

If a VDRL result is positive, the health care provider requests or the laboratory may automatically perform a more specific treponemal test, such as the *fluorescent treponemal antibody absorption (FTA-ABS)* test or the *microhemagglutination assay for T. palladium (MHA-TP)*, to confirm the infection. These tests are more sensitive for all stages of syphilis, although false-positive results may still occur. Patients who have a reactive test will have this positive result for their entire life, even after sufficient treatment. This poses a challenge

when receiving a positive result for a patient who denies a history of or does not know he or she had syphilis.

INTERVENTIONS

Patient-centered collaborative care includes drug therapy and health teaching to resolve the infection and prevent infection transmission to others.

Drug Therapy

Benzathine penicillin G given IM as a single 2.4 million-unit dose is the evidence-based treatment for primary, secondary, and early latent syphilis (CDC, 2010a). Patients in the late latent stage receive the same dose every week for 3 weeks (CDC, 2010a).

! NURSING SAFETY PRIORITY

Drug Alert

Allergic reactions to benzathine penicillin G can occur. Therefore monitor for allergic manifestations (e.g., rash, edema, shortness of breath, chest tightness, anxiety). Be sure that the patient who has never had penicillin has a skin test before receiving the injection. Penicillin desensitization is recommended for penicillin-allergic patients. Keep all patients at the health care agency for at least 30 minutes after they have received the antibiotic so that manifestations of an allergic reaction can be detected and treated. The most severe reaction is anaphylaxis. Treatment should be available and implemented immediately if symptoms occur. Chapter 19 describes the management of drug allergies in detail.

After treatment, the CDC recommends follow-up evaluation including blood tests at 6, 12, and 24 months. Repeat treatment may be needed if the patient does not respond to the initial antibiotic.

The *Jarisch-Herxheimer reaction* may also follow antibiotic therapy for syphilis. This reaction is caused by the rapid release of products from the disruption of the cells of the organism. Symptoms include generalized aches, pain at the injection site, vasodilation, hypotension, and fever. They are usually benign and begin within 2 hours after therapy with a peak at 4 to 8 hours. This reaction may be treated symptomatically with analgesics and antipyretics.

Teaching for Self-Management

Reinforce teaching about the cause of infection (sexual transmission); treatment, including side effects; possible complications of untreated or incompletely treated disease; and the need for follow-up care.

! NURSING SAFETY PRIORITY

Drug Alert

Discuss with the patient with syphilis the importance of partner notification and treatment, including the risk for re-infection if the partner goes untreated. All sexual partners must be prophylactically treated as soon as possible, preferably within 90 days of the syphilis diagnosis.

Inform the patient that the disease will be reported to the local health authority and that all information will be held in strict confidence. Encourage the patient to provide accurate information for this follow-up to ensure that all at-risk partners are treated appropriately. Provide a setting that offers

privacy and encourages open discussion. Urge the patient to adhere to the treatment regimen, which includes follow-up visits. Also recommend sexual abstinence until the treatment of both the patient and partner(s) is completed.

The emotional responses to syphilis vary and may include feelings of fear, depression, guilt, and anxiety. Patients may experience guilt if they have infected others or anger if they have been infected by a partner. If further psychosocial interventions are needed, encourage the patient to discuss these feelings or refer him or her to other resources such as psychotherapy groups, self-help support groups, or STD clinics.

NCLEX EXAMINATION CHALLENGE

Physiological Integrity

The nurse gives a client an IM dose of penicillin G for syphilis. What is the priority action for the nurse after giving the drug?

- A. Monitor the client for at least 30 minutes for any reaction to the drug.
- B. Rub the site with an alcohol prep to ensure even distribution of the drug.
- C. Teach the client the importance of not having sexual intercourse for 7 days.
- D. Ask the client if she is allergic to any drugs, especially penicillin.

GENITAL HERPES

Pathophysiology

Genital herpes (GH) is an acute, recurring, incurable viral disease. It is the most common STD in the United States, with 16.2% of Americans currently infected with herpes simplex virus type 2 (HSV-2). The prevalence among African Americans is 39.2%, disproportionately affecting African-American women (48.0%) (CDC, 2010b). These rates are based on the presence of HSV-2 antibodies in the blood of those tested, the majority of whom have had no symptoms and most have never received a diagnosis of GH infection (CDC, 2010b).

Two serotypes of herpes simplex virus (HSV) affect the genitalia: type 1 (HSV-1) and type 2 (HSV-2). Most *nongenital* lesions such as cold sores are caused by HSV-1. Historically, HSV-2 caused most of the genital lesions. However, this distinction is academic because the transmission, symptoms, diagnosis, and treatment are nearly identical for the two types. Either type can produce oral or genital lesions through oral-genital contact with an infected person. HSV-2 has been thought to cause the majority of the primary episodes of GH, though up to one-third are caused by HSV-1 (Drugge & Allen, 2008). HSV-2 recurs and sheds asymptotically more often than HSV-1. Most people with GH have not been diagnosed because they have mild symptoms and shed virus intermittently (CDC, 2010a).

The incubation period of genital herpes is 2 to 20 days, with the average period being 1 week. Many people do not have symptoms during the primary outbreak. When outbreaks occur, they are usually more severe than in recurrent outbreaks and occasionally require hospitalization.

Recurrences are not caused by re-infection. Additional episodes are usually less severe and of shorter duration than the primary infection episode. Some patients have no symptoms at all during recurrence or viral reactivation. *However, there is viral shedding and the patient is infectious.* Long-term

complications of GH include the risk for neonatal transmission and an increased risk for acquiring HIV infection.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

The diagnosis of GH is usually based on the patient's history and physical examination (see [Chart 76-1](#)). Ask the patient if he or she felt itching or a tingling sensation in the skin 1 to 2 days before the outbreak. These sensations are usually followed by the appearance of **vesicles** (blisters) in a typical cluster on the penis, scrotum, vulva, vagina, cervix, or perianal region. The blisters rupture spontaneously in a day or two and leave painful erosions that can become extensive. Assess for other symptoms such as headaches, fever, general malaise, and swelling of inguinal lymph nodes. Ask if urination is painful. Patients with urinary retention may need to be catheterized. Lesions resolve within 2 to 6 weeks.

After the lesions heal, the virus remains in a dormant state in the nerve ganglia (specifically, the sacral ganglia). Periodically, the virus may activate and symptoms recur. These recurrences may be triggered by many factors, including stress, fever, sunburn, poor nutrition, menses, and sexual activity. Assess the patient for these risk factors.

GH is confirmed through a viral culture or polymerase chain reaction (PCR) assays of the lesions. PCR is the more sensitive test. Fluid from inside the blister should be obtained within 48 hours of the first outbreak of the blisters, since accuracy decreases as they begin to heal. Serology testing, which is glycoprotein G antibody-based, can identify the HSV type, either 1 or 2. Serologic tests are used to identify infection in high-risk groups such as HIV-positive patients, patients who have partners with HSV, or MSM ([CDC, 2010a](#)). The POckit HSV-2 Rapid Test is a point-of-care test with results in 6 minutes. The HerpeSelect Immunoblot IgG test, HerpeSelect ELISA, and the Western Blot are qualitative assays that can differentiate between HSV-1 and HSV-2. All of these tests are highly specific and sensitive (Bavis et al., 2009).

INTERVENTIONS

The desired outcomes of treatment for HSV-infected patients are to decrease the discomfort from painful ulcerations, promote healing without secondary infection, decrease viral shedding, and prevent infection transmission ([Chart 76-2](#)).

Drug Therapy

Antiviral drugs are used to treat GH. *The drugs do not cure the infection but do decrease the severity, promote healing, and decrease the frequency of recurrent outbreaks while they are being used.*

Drug therapy should be offered to anyone with an initial outbreak of GH. Though the initial symptoms may be mild, they may become more severe. Topical therapy is not recommended. Acyclovir (Zovirax, Avirax ) , famciclovir (Famvir), or valacyclovir (Valtrex) may be prescribed. The main differences in these drugs are cost and frequency of use. Dosage and length of treatment differ for primary outbreaks (lasting 7 to 10 days) and recurrent outbreaks (lasting 1 to 5 days). Intermittent or continuous suppressive antiviral therapy is offered to patients to lessen or prevent outbreaks, even for

CHART 76-2 BEST PRACTICE FOR PATIENT SAFETY & QUALITY CARE

Care of or Self-Management for the Patient with Genital Herpes

- Administer oral analgesics as prescribed.
- Apply local anesthetic sprays or ointments as prescribed.
- Apply ice packs or warm compresses to the patient's lesions.
- Administer sitz baths three or four times a day.
- Encourage an increase in fluid intake to replace fluid lost through open lesions.
- Encourage frequent urination.
- Pour water over the patient's genitalia while voiding, or encourage voiding while the patient is sitting in a tub of water or standing in a shower.
- Catheterize the patient as necessary.
- Encourage genital hygiene, and encourage keeping the skin clean and dry.
- Wash hands thoroughly after contact with lesions, and launder towels that have had direct contact with lesions.
- Wear gloves when applying ointments or making any direct contact with lesions.
- Advise the patient to avoid sexual activity when lesions are present.
- Advise the patient to use latex or polyurethane condoms during all sexual exposures.
- Instruct the patient in the use, side effects, and risks versus benefits of antiviral agents.
- Advise the patient to discuss the diagnosis of genital herpes (GH) with current and new partners.

those with infrequent recurrent episodes. Therapy for severe recurrent outbreaks is most beneficial if it is started within 1 day of the appearance of lesions or during the period of itching or tingling before lesions appear.

Patients who have recurrences, regardless of frequency, may benefit from daily suppressive treatment. Suppression reduces recurrences in most patients, but it does not prevent viral shedding, even when symptoms are absent ([CDC, 2010a](#)). Patients receiving continuous therapy should periodically (possibly once a year) be reassessed for recurrences, usually by stopping the antiviral drug temporarily.

IV acyclovir and hospitalization may be indicated for patients with severe HSV infections, such as disseminated disease or encephalitis. These are severe complications of genital herpes and may be fatal.

Teaching for Self-Management

Nursing interventions focus on patient counseling and education about the infection, the potential for recurrent episodes, the correct use and possible side effects of antiviral therapy, and sexual transmission. Discussion about sexual activity is extremely important.

! NURSING SAFETY PRIORITY

Action Alert

Remind patients to abstain from sexual activity while GH lesions are present. Urge condom use during all sexual exposures because of the increased risk for HSV transmission. Viral shedding can occur even when lesions are not present. Teach the patient about how and when to use condoms ([Chart 76-3](#)).

CHART 76-3 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Use of Condoms

- Use latex or polyurethane condoms rather than natural membrane condoms.
- Use a condom with every sexual encounter (including oral, vaginal, and anal).
- Female condoms (Reality)—polyurethane or nitrile sheaths in the vagina—are effective in preventing transmission of viruses, including HIV.
- Condoms infrequently (2 per 100) break during sexual intercourse.
- Keep condoms (especially latex) in a cool, dry place, out of direct sunlight.
- Do not use condoms that are in damaged packages or that are brittle or discolored.
- Always handle a condom with care to avoid damaging it with fingernails, teeth, or other sharp objects.
- Put condoms on before any genital contact. Hold the condom by the tip and unroll it on the penis. Leave a space at the tip to collect semen.
- If you use a lubricant with condoms, make sure that the lubricant is water based and washes away with water. Oil-based products damage latex condoms.
- Use of spermicide (nonoxonyl-9) with condoms, either lubricated condoms or vaginal application, has *not* been proven to be more or less effective against STDs than use without spermicide. *Spermicide-coated condoms have been associated with Escherichia coli urinary tract infections in women. Nonoxonyl-9 may increase risk for transmission of HIV during vaginal intercourse and anal intercourse. Its use is discouraged for anal intercourse.*
- If a condom breaks, replace it immediately.
- After ejaculation, withdraw the erect penis carefully, holding the condom at the base of the penis to prevent the condom from slipping off.
- Never use a condom more than once.

Modified from Centers for Disease Control and Prevention (CDC). (2010a). Sexually transmitted diseases treatment guidelines, 2010. *Morbidity and Mortality Weekly Report*, 59(RR-12), 4-5.

HIV, Human immune deficiency virus; STDs, sexually transmitted diseases.

Assess the patient's and partner's emotional responses to the diagnosis of genital herpes. Many people are initially shocked and need reassurance that they can manage the disease. Infected patients may have feelings of disbelief, uncleanness, isolation, and loneliness. They may also be angry at their partners for transmitting the infection or fear rejection by partners because they have the infection. Help patients cope with the diagnosis by being sensitive and supportive during assessments and interventions. Encourage social support, and refer patients to support groups (e.g., local support groups of the National Herpes Resource Center [www.ashstd.org/herpes/herpes_comm_support.cfm]). Symptomatic care may include oral analgesics, topical anesthetics, sitz baths, and increased oral fluid intake (Bavis et al., 2009).

Emphasize the risk for neonatal infection to all patients, both male and female. Men and women who have genital herpes need to inform the pregnancy care provider of their history. Infected male partners will be advised to avoid intercourse during pregnancy if the pregnant partner is not infected. This avoids the risk for a new primary infection and outbreak during pregnancy. People who have tested serology

positive to HSV-1 or HSV-2 but have never had GH symptoms should be counseled with the same information as those who have symptoms (CDC, 2010a).

INFECTIONS OF THE EPITHELIAL STRUCTURES

CONDYLOMATA ACUMINATA (GENITAL WARTS)

Pathophysiology

Condylomata acuminata (also known as *genital warts*) are caused by certain types of *human papilloma virus* (HPV), 90% of which are types 6 and 11 or low-risk HPV (Winer & Koutsky, 2008). These types *rarely* result in invasive cancer of the genital tract such as cervical cancer. *However, HPV types 16, 18, 31, 33, and 35, considered high-risk HPV, can be found on the skin of the genitalia and increase the risk for genital cancers, especially cervical cancer.* Infection with several HPV types can occur at the same time. The presence of one strain increases the risk for acquiring a higher-risk strain. Genital warts are the most common viral disease that is sexually transmitted and are often seen with other infections. Many American women, ages 14 to 59 years, are infected with either high- or low-risk HPV (Dunne et al., 2007).

HPV infection is thought to be the primary risk factor for development of cervical cancer (Winer & Koutsky, 2008). Sites commonly affected by infection include the urinary meatus, labia, vagina, cervix, penis, scrotum, anus, and perineal area. The incubation period is usually 2 to 3 months. There is growing evidence that HPV infection through oral and anal sex, especially in men who have sex with men (MSM), may be a risk factor for developing oral and anal cancers (Chaturvedi et al., 2008; Kim, 2010).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

The diagnosis of condylomata acuminata is made by examination of the lesions. They are initially small, white or flesh-colored papillary growths that may grow into large cauliflower-like masses (Fig. 76-2). Multiple warts usually occur in the same area. Bleeding may occur if the wart is disturbed. Warts may disappear or resolve on their own without treatment. They may occur once or recur at the original site.

A Papanicolaou (Pap) test and HPV DNA probe are used to obtain cervical specimens to assess for dysplasia and isolate and diagnose HPV of the cervix. High-risk strains of HPV can be identified and correlated with an abnormal Pap smear finding. High-risk HPV may co-exist with low-risk HPV, the likely cause of the warts. To rule out the presence of other STDs, a VDRL test, HIV test, and cultures for chlamydia and gonorrhea infections are done. If a wartlike lesion bleeds easily, appears infected, is atypical, or persists, a biopsy of the lesion is performed to rule out other pathologic problems such as cancer.

INTERVENTIONS

The desired outcomes of management are to remove the warts and treat the symptoms. No current therapy eliminates HPV. Therefore recurrences after treatment are likely. It is not

FIG. 76-2 Perianal condylomata acuminata.

known whether removal of visible warts decreases the risk for disease transmission (CDC, 2010a).

Drug Therapy

Patients may apply podofilox (Condylox) 0.5% cream or gel twice daily for 3 days with no treatment for the next 4 days. This regimen should be repeated for four cycles. Other options are imiquimod (Aldara) 5% cream applied topically at bedtime three times a week and sinecatechins 15% ointment applied three times a day, both until the warts disappear or for up to 16 weeks. Imiquimod boosts the immune system rather than simply destroying the warts. These self-treatments are less expensive than those performed in the health care provider's office, but they take longer for healing. *Teach patients that over-the-counter (OTC) wart treatments should not be used on genital tissue* (CDC, 2010a).

Cryotherapy, trichloroacetic acid (TCA) or bichloroacetic acid (BCA), and podophyllin (Pododerm) are provider-applied treatments. **Cryotherapy** (freezing), usually with liquid nitrogen, can be used every 1 to 2 weeks until lesions are resolved. TCA/BCA (80% to 90%) can be applied weekly. Podophyllin resin can be applied weekly but needs to be washed off 1 to 4 hours after application. Extensive warts have been treated with the carbon dioxide laser, intra-lesion interferon injections, and surgical removal (CDC, 2010a).

Teaching for Self-Management

The priority for nursing management is patient and sexual partner education about the mode of transmission, incubation period, treatment, and complications, especially the association with cervical cancer. Reinforce instructions about local care of the lesions or patient-applied treatment for self-management.

Inform patients that recurrence is likely, especially in the first 3 months, and that repeated treatments may be needed. Urge all patients to have complete STD testing, since exposure to one may increase risk for contracting another.

! NURSING SAFETY PRIORITY

Drug Alert

Teach patients that after treatment with cryotherapy, podophyllin, or TCA, they may experience discomfort, bleeding, or discharge from the site or sloughing of parts of warts. Instruct patients to keep the area clean (shower or bath) and dry. Teach them to be alert for any signs or symptoms of infection or side effects of the treatment.

Condylomata lata (secondary syphilis) can resemble condylomata acuminata (genital warts). Sexual partners should also be evaluated and offered treatment if warts are present. Teach patients to avoid intimate sexual contact until external lesions are healed. Recommend condoms to help reduce transmission even after warts have been treated (see Chart 76-3). Encourage women to have an annual Pap test. The presence of warts requires HPV testing of the patient and partner.

In 2006, the U.S. Food and Drug Administration (FDA) approved an HPV vaccine *Gardasil*® (Merck) that provides almost 100% immunity for HPV types 6 and 11 (predominantly types causing warts, low risk for cervical cancer) and 16 and 18 (high risk for cervical cancer). The vaccine was approved for females initially. In 2010, it was approved for males ages 9 to 26 years as a method for reducing cervical cancer. In 2009, CERVARIX® (GSK) was approved for 10- to 25-year-old females and protects only against HPV types 16 and 18. Both vaccines are recommended to be given before onset of sexual activity before there may be contact with HPV. They are also effective in protecting against infection if exposed to a second strain later. Early results have suggested that rates of genital warts and cervical cancer will be significantly lowered by these vaccines (Muñoz et al., 2010).

GONORRHEA

Pathophysiology

Gonorrhea is a sexually transmitted bacterial infection that occurs in both men and women. The causative organism is *Neisseria gonorrhoeae*, a gram-negative intracellular diplococcus. It is transmitted by direct sexual contact with mucosal surfaces (vaginal intercourse, orogenital contact, or anogenital contact).

The first symptoms of gonorrhea may appear 3 to 10 days after sexual contact with an infected person. The disease can be present without symptoms and can be transmitted or progress without warning. In women, ascending spread of the organism can cause pelvic infection (**pelvic inflammatory disease [PID]**), **endometritis** (endometrial infection), **salpingitis** (fallopian tube infection), and pelvic peritonitis. Rare complications of gonorrhea in adults include arthritis, meningitis, hepatitis, and disseminated infection.

An estimated 700,000 new infections occur each year, only half of which are diagnosed or reported (CDC, 2010a). Significant disparity exists between age and racial groups. In 2008, young African-American women had the highest gonorrhea rate, followed by young African-American men (CDC, 2009). The reasons for these differences are not known, although lack of access to health care may be a factor.

Over the years, gonorrhea has become resistant to penicillin, tetracycline, and ciprofloxacin. Ciprofloxacin is no longer the drug of choice because of the development of fluoroquinolone-resistant *N. gonorrhoeae* (CDC, 2007a).

FIG. 76-3 Areas of involvement of gonorrhea in men and women.

Cephalosporins are currently the only class of antibiotics that have not developed gonorrhea resistance (CDC, 2010c).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

A complete history includes reviewing possible symptoms of gonorrhea and taking a sexual history that includes sexual orientation and sites of sexual exposure or intercourse. Assess for allergies to antibiotics (see Chart 76-1). Establish a trusting relationship and use a nonjudgmental approach to gather more complete information. This approach may decrease the patient's anxiety and fear about having an STD.

The infection can be asymptomatic in both men and women, but women have asymptomatic, or "silent," infections more often than do men. If symptoms are present, men usually notice dysuria and a penile discharge that can be either profuse yellowish green fluid or scant clear fluid. The urethra is most commonly affected, but infection can extend to the prostate, the seminal vesicles, and the epididymis. Men seek curative treatment sooner, usually because they have

symptoms, and thereby avoid some of the serious complications.

Women may report a change in vaginal discharge (yellow, green, profuse, odorous), urinary frequency, or dysuria. The cervix and urethra are the most common sites of infection.

Anal manifestations may include itching and irritation, rectal bleeding or diarrhea, and painful defecation. Assess the mouth for a reddened throat, ulcerated lips, tender gingivae, and blisters in the throat. Fig. 76-3 shows common sites of gonococcal infections.

Inspect for discharge from the urethra, cervix, and rectum. Palpation of the lower abdomen may reveal tenderness. Fever may be present, especially if an ascending or systemic infection has occurred. Gonorrheal infections that have become systemic may develop quickly. Manifestations of disseminated gonococcal infection (DGI) include fever, chills, skin lesions on distal extremities, and joint pain, with or without swelling, heat, or redness.

Clinical symptoms of gonorrhea can resemble those of chlamydia infection and therefore need to be differentiated. *Molecular testing for N. gonorrhoeae is currently the most widely used standard and preferred over cultures or*

microscopic examinations. These nucleic acid amplification tests (NAATs) are highly sensitive and specific. During examination, providers can swab the male urethra or female cervix to obtain specimens. These specimens can be cultured on chocolate agar (gold standard), viewed microscopically after Gram staining (male urethral specimens only), or placed in medium for molecular testing. Patient-collected urine or vaginal swabs can also be used to diagnose both gonorrhea and chlamydia infections, allowing for screening without a full examination.

In men, gonorrhea can be diagnosed by Gram staining smears of urethral discharge that has been swabbed onto a glass slide, dried, and stained. The presence of gram-negative diplococci is diagnostic for gonococcal urethritis in men. If the man has symptoms, Gram stains are very sensitive and specific for gonorrhea and allow for immediate diagnosis and treatment in the clinical setting. Without symptoms, Gram stains are less reliable. Smears do not confirm the diagnosis in women because the female genital tract normally harbors organisms that resemble *N. gonorrhoeae*.

All patients with gonorrhea should be tested for HPV, syphilis, chlamydia, hepatitis B and hepatitis C, and HIV infection because they may have been exposed to these STDs as well. Sexual partners who have been exposed in the past 30 days should be examined, and specimens should be obtained.

INTERVENTIONS

Uncomplicated gonorrhea is treated with antibiotics. Chlamydia infections are frequently found in patients with gonorrhea. Patients treated for gonorrhea should also be managed with drugs that treat chlamydia infections.

Drug Therapy

Drug therapy recommended by the CDC is ceftriaxone (Rocephin) 250 mg IM or cefixime (Suprax) 400 mg orally in a single dose, *plus* azithromycin (Zithromax) 1 g orally in a single dose or doxycycline (Monodox, Doxy-Caps, Doxycine) 100 mg orally twice daily for 1 week to treat a presumed co-infection with *Chlamydia*, unless a negative *Chlamydia* result has been obtained. These combinations seem to be effective for all mucosal gonorrheal infections; treatment failure is rare (CDC, 2010a). The CDC recommends the ceftriaxone injection because the treatment is given at the point of care, which increases drug adherence and is slightly more effective than cefixime (CDC, 2010a). A test of cure is not required. Advise the patient to return for a follow-up examination if symptoms persist after treatment. Re-infection is often the cause of these symptoms.

Sexual partners must be treated, not only evaluated, to prevent re-infection. Sexual partners also need to receive education about the infection.

A newer approach to preventing recurrence or persistent infections of STDs is expedited partner therapy (EPT), which is providing patients with newly diagnosed gonorrhea or other STD treatment for their partners. Patients are given the antibiotic or a prescription with specific instructions for administration to their partners without direct evaluation by a health care provider (CDC, 2010a). Legal questions have arisen about whether a drug can be prescribed without a relationship between the health care provider and the patient (CDC, 2010e). When patients have been given the drug to give to their partner, rates of infection have decreased and

more partners have reported receiving treatment (Trelle et al., 2007).

Gonorrhea infection can become disseminated (DGI) requiring hospitalization and IV or IM ceftriaxone 1 g every 24 hours. If symptoms resolve within 24 to 48 hours, the patient may be discharged to home to continue oral antibiotic therapy (cefixime 400 mg twice a day) for at least a week (CDC, 2010a).

Meningitis and endocarditis occur rarely. Hospitalization of patients with these problems is recommended for the initial treatment. Treatment includes IV antibiotic therapy, usually ceftriaxone 1 to 2 g every 12 hours. If meningitis or endocarditis is present, therapy is continued for 10 to 14 days for meningitis and at least 4 weeks for endocarditis. Collaborate with the infectious disease specialist for management of these infections.

Teaching for Self-Management

Teach the patient about transmission and treatment of gonorrhea. Patients must understand the need for drugs to be taken for the prescribed time for maximum effectiveness and to prevent drug resistance. Discuss the possibility of re-infection, including the risk for pelvic inflammatory disease (PID), and resultant problems such as ectopic pregnancy, infertility, and chronic pelvic pain. Instruct patients to cease sexual activity until the antibiotic therapy is completed and they no longer have symptoms; but if abstinence is not possible, urge men and women to use condoms. Explain that gonorrhea is a *reportable disease*.

When a diagnosis of gonorrhea is made, patients may have feelings of fear or guilt. They may be concerned that they have contracted other STDs or see the disease as a punishment for promiscuity or “unnatural” sex acts. They may believe that

DECISION-MAKING CHALLENGE

Patient-Centered Care; Teamwork and Collaboration

A 49-year-old woman develops a heavy greenish vaginal discharge with a very foul odor. She visits her gynecologist, who tells her that she has gonorrhea. When the patient learns how the infection is transmitted, she tells her physician that she has not “slept with any other man” since she was married 29 years ago and that the diagnosis cannot be correct. When her husband returns home from work, she confronts him about her diagnosis. He initially denies that he has had sex with any other woman but then confesses that he has been “seeing” a young woman who works at his store for about 3 months. He admits that he has symptoms of the infection, too. The patient is very upset and returns to her gynecologist in 1 week. Her husband refuses to come with her. She tells you, the office nurse, that she just can’t understand how her husband can be so unfaithful after all the years they have had together. She is considering filing for a divorce, but she is worried about her three children, ranging in age from 28 to 15.

1. What is the most appropriate way for you to respond to the patient at this time?
2. You tell the patient that her husband and the young woman involved need to be treated for the disease, and suggest expedited partner therapy. How will you explain this treatment method?
3. The patient tells you that she “never wants to meet that slut who stole my husband.” How will you respond to this statement?
4. What emotional feelings is this patient experiencing? Develop a collaborative plan of care for this patient to ensure that desired patient and family outcomes will be met.

acquiring gonorrhea (or any STD) is a risk that they must take to pursue their desired lifestyle. Such feelings can impair relationships with sexual partners. Encourage patients to express their feelings during assessments and teaching sessions. Ensuring privacy for teaching and maintaining confidentiality of medical records are essential in meeting psychosocial needs.

CHLAMYDIA INFECTION

Pathophysiology

Chlamydia trachomatis is an intracellular bacterium and the causative agent of genital chlamydia infections. It invades the epithelial tissues in the reproductive tract. The incubation period ranges from 1 to 3 weeks, but the pathogen may be present in the genital tract for months without producing symptoms (Stamm, 2008a).

C. trachomatis is reportable to local health departments in all states. Diagnosed cases continue to increase yearly, which reflects more sensitive screening tests and increased public health efforts to screen high-risk people. Each year there are an estimated 2.8 million new cases in the United States (CDC, 2009). African-American women between 16 and 24 years of age are at the highest risk for the disease (CDC, 2009).

The rate of chlamydia infections in men has increased faster than the rate of increase in women (CDC, 2009). In women, 20% to 40% of those infected develop pelvic inflammatory disease (PID), discussed later in this chapter on p. 1663.

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

Obtain a complete history including medical, menstrual, and sexual information (see Chart 76-1). In particular, ask about:

- Presence of symptoms, including vaginal or urethral discharge, **dysuria** (painful urination), pelvic pain, irregular bleeding
- Any history of sexually transmitted diseases (STDs)
- Whether sexual partners have had symptoms or a history of STDs
- Whether patient or partner has had unprotected intercourse

Many women with chlamydia infections are asymptomatic. For men and women, their history may reveal only risk factors associated with *C. trachomatis*, such as new or multiple sexual partners, age younger than 26 years and female, or a male having sex with a male (MSM). As with all interviews concerning sexual behavior, use a nonjudgmental approach and provide privacy and confidentiality.

! NURSING SAFETY PRIORITY

Action Alert

For men, ask about dysuria, frequent urination, and a mucoid discharge that is more watery and less copious than a gonorrheal discharge. *These manifestations indicate urethritis, the main symptom of chlamydia infection in men.* Some men have the discharge only in the morning on arising. Complications include epididymitis, prostatitis, infertility, and Reiter's syndrome, a type of connective tissue disease discussed in Chapter 20.

In contrast, many women have no symptoms. Those with symptoms have a mucopurulent cervicitis with a change in vaginal discharge, easily induced cervical bleeding presenting as spotting or bleeding between menses, urinary frequency, and abdominal discomfort or pain. The vaginal discharge typically becomes yellow and more opaque. Complications of infection with *C. trachomatis* include salpingitis (inflammation of the fallopian tubes), PID, ectopic pregnancy, and infertility. These health problems are discussed in detail in maternal-child textbooks.

Diagnosis is made by sampling cells from the endocervix, urethra, or both, easily obtained with a swab. Because chlamydiae can reproduce only inside cells, host cells that harbor the organism (or parts of it) are required in the sample. Diagnosis is made definitively with a tissue culture (gold standard) obtained from the cervical os during the female pelvic examination or male urethral examination.

As with gonorrhea, the nucleic acid amplification tests (NAATs) and gene amplification tests (ligand chain reaction [LCR] and polymerase chain reaction [PCR] transcription-mediated amplification) are the newest methods of detecting *Chlamydia* in endocervical samples, urethral swabs, and urine. Samples can be obtained by swab by the examining clinician or by a patient-collected urine specimen. This urine self-collection method has been found to be more acceptable and highly sensitive and specific. The acceptability of urine testing has resulted in increased identification of asymptomatic people.

All sexually active women 25 years old or younger and all women older than 25 years with new or multiple partners should be screened annually for *Chlamydia* (CDC, 2010a). There is no recommendation for or against screening asymptomatic men, regardless of age or other risk, and low-risk asymptomatic women.

INTERVENTIONS

The treatment of choice for chlamydia infections is azithromycin (Zithromax) 1 g orally in a single dose or doxycycline (Monodox, Doxy-Caps, Doxycin) 100 mg orally twice daily for 7 days. The one-dose course, although more expensive, is preferred because of the ease in completing the treatment. Drugs that are prescribed for patients with allergies to these drugs include erythromycin, ofloxacin, and levofloxacin, all for 7 days (CDC, 2010a).

Giving the drug while the patient is in the health care agency helps ensure adherence. Sexual partners should be treated and tested for other STDs. **Expedited partner therapy (EPT)**, or patient-delivered partner therapy, shows signs of reducing chlamydia infection rates (CDC, 2010a).

Patient and partner education is an important nursing intervention. Explain:

- The mode of disease transmission
- The incubation period
- Manifestations, including the high possibility of asymptomatic infections
- Treatment of infection with antibiotics
- The need for abstinence from sexual intercourse until the patient and partner(s) have completed treatment (7 days from the start of treatment, including a single-dose regimen)
- No test of cure is required, but all women should be re-screened for re-infection 3 to 12 months after

treatment because of the high risk for PID. There is less evidence of the need for re-screening of treated men, but it should be considered

- The need to return for evaluation if symptoms recur or new symptoms develop (most recurrences are re-infections from a new or untreated partner)
- Possible complications of untreated or inadequately treated infection, such as PID, ectopic pregnancy, or infertility

OTHER GYNECOLOGIC CONDITIONS

PELVIC INFLAMMATORY DISEASE

Pathophysiology

Pelvic inflammatory disease (PID) is a complex infectious process in which organisms from the lower genital tract migrate from the endocervix upward through the uterine cavity into the fallopian tubes. The spread of infection to other organs and tissues of the upper genital tract occurs from direct contact with mucosal surfaces or through the fimbriated ends of the tubes to the ovaries, parametrium, and peritoneal cavity (Fig. 76-4). This may involve one or more pelvic structures, including the uterus, fallopian tubes, and adjacent pelvic structures. The most common site is the fallopian tube. Resulting infections include:

- Endometritis (infection of the endometrial cavity)
- Salpingitis (inflammation of the fallopian tubes)
- Oophoritis (ovarian infection)
- Parametritis (infection of the parametrium)
- Peritonitis (infection of the peritoneal cavity)
- Tubal or tubo-ovarian abscess

Many different pathogens are linked to PID. Sexually transmitted organisms are most often responsible, especially *Chlamydia trachomatis* and *Neisseria gonorrhoeae*. Organisms that

are part of the vaginal flora can also cause PID. In addition, *Gardnerella vaginalis*, *Haemophilus influenzae*, *Staphylococcus*, *Streptococcus*, *Escherichia coli*, and other aerobic and anaerobic organisms have been identified in patients with PID. There is increasing evidence that the anaerobes involved in bacterial vaginosis may have a role in the development of PID and increase the risk for infection with HIV, *N. gonorrhoea*, *C. trachomatis*, and HSV (CDC, 2010a).

The organisms invade the pelvis from an infection ascending from the vagina or cervix. Infections are spread during sexual intercourse, during childbirth (including the postpartum period), and after abortion. Rarely do they result from transperitoneal spread from a ruptured appendix or intra-abdominal abscess. *Sepsis and death can occur, especially if treatment is delayed or inadequate.*

Many practitioners use the terms *PID* and *salpingitis* as equal terms for acute infections. PID is one of the leading causes of infertility and is related to the increase in the number of ectopic pregnancies reported in the United States. It is an acute syndrome resulting in tenderness in the tubes and ovaries (adnexa) and low, dull abdominal pain. However, many women experience only mild discomfort or menstrual irregularity. Others experience no symptoms at all—so-called “silent” or “subclinical” PID. The diagnosis and treatment of this disease are challenging. Irreversible scarring or stricture, causing sterility, may occur before it is diagnosed.

Because of variations in patient manifestations, the diagnosis is difficult because women may have subtle symptoms not typical of the disease. Delay in diagnosis and treatment may add to complications of PID in the upper genital tract. The disease is usually diagnosed on the basis of clinical signs and symptoms. The **Centers for Disease Control and Prevention (CDC)** (2010d) has set minimum criteria for diagnosis, but no laboratory or physical examination techniques alone are both sensitive and specific (Table 76-4).

PATIENT-CENTERED COLLABORATIVE CARE

ASSESSMENT

History

Obtain a complete medical, family, menstrual, obstetric, and sexual history, including a history of previous episodes of pelvic inflammatory disease (PID) or other sexually transmitted diseases (see Chart 76-1). Assess for contraceptive use, a history of reproductive surgery, and other risk factors previously identified. Ask the patient if sexual abuse has occurred. If so, encourage her to discuss what happened and whether she was seen by a health care provider.

Many of the same factors that place women at risk for STDs also place them at risk for PID. Risk factors for sexually active women include:

- Age younger than 26 years
- Multiple sexual partners
- Intrauterine device (IUD) placed within the previous 3 weeks
- Smoking
- A history of PID
- Chlamydial or gonococcal infection; bacterial vaginosis
- A history of sexually transmitted diseases (STDs)

FIG. 76-4 The spread of pelvic inflammatory disease.

TABLE 76-4 DIAGNOSTIC CRITERIA FOR PELVIC INFLAMMATORY DISEASE**Minimum Criteria for Initiating Empiric Treatment for Pelvic Inflammatory Disease**

- Sexually active woman and at risk for STDs
- Pelvic or lower abdominal pain
- No other cause for illness can be found (e.g., appendicitis)

and

- Uterine tenderness or
- Adnexal tenderness or
- Cervical motion tenderness (chandelier sign)

Additional Criteria to Increase the Specificity of the Diagnosis of PID

- Oral temperature $>101^{\circ}\text{F}$ ($>38.3^{\circ}\text{C}$)
- Abnormal cervical or vaginal mucopurulent discharge
- Presence of white blood cells on saline microscopy of vaginal secretions
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein
- Laboratory documentation of cervical infection with *Neisseria gonorrhoeae* or *Chlamydia trachomatis*

Definitive Criteria for Diagnosing PID, Warranted in Selected Cases

- Histopathologic evidence of endometritis on endometrial biopsy
- Transvaginal sonography or magnetic resonance imaging techniques showing thickened fluid-filled tubes with or without free pelvic fluid or tubo-ovarian complex, or Doppler studies suggesting pelvic infection
- Laparoscopic abnormalities consistent with PID

Modified from Centers for Disease Control and Prevention (CDC). (2010a). Sexually transmitted diseases treatment guidelines, 2010. *Morbidity and Mortality Weekly Report*, 59(RR-12), 63-64.

PID, Pelvic inflammatory disease; STDs, sexually transmitted diseases.

Physical Assessment/Clinical Manifestations

One of the most frequent symptoms of PID is lower abdominal pain. Conduct a complete pain assessment. Other symptoms include irregular vaginal bleeding (spotting or bleeding between periods), dysuria (painful urination), an increase or change in vaginal discharge, dyspareunia (painful sexual intercourse), malaise, fever, and chills.

Observe whether the patient has discomfort with movement. Often the patient has a hunched-over gait to protect her abdomen. She may find it difficult to independently get on the examination table or stretcher. Assess for lower abdominal tenderness, possibly with rigidity or rebound tenderness. A pelvic examination by the health care provider may reveal yellow or green cervical discharge and a reddened or friable cervix (a cervix that bleeds easily). Criteria for accurate diagnosis of PID are listed in Table 76-4. The diagnosis of PID is usually based on clinical history, physical examination, and laboratory tests. Imaging studies and laparoscopy are not generally used to make the diagnosis.

Psychosocial Assessment

The woman who has symptoms of PID is usually anxious and fearful of the examination and unknown diagnosis. She may need much reassurance and support during the physical examination because her abdomen may be very tender or painful. Explain what is taking place to help promote comfort during the examination.

Because PID is often associated with an STD, the woman may feel embarrassed or uncomfortable discussing her

symptoms or history. Use a nonjudgmental approach, and encourage the patient to express her feelings and concerns. The patient's ability to follow through with the treatment plan is essential in deciding whether ambulatory care treatment is appropriate.

Laboratory Assessment

The health care provider obtains specimens from the cervix, urethra, and rectum to determine the presence of *N. gonorrhoeae* or *C. trachomatis*. The white blood cell (WBC) count, erythrocyte sedimentation rate (ESR) and C-reactive protein may be elevated but are not specific for PID. A sensitive test that detects human chorionic gonadotropin (hCG) in urine or blood should be performed to determine whether the patient is pregnant. Microscopic examination of vaginal discharge should be done to evaluate for the presence of more than 10 WBCs per high-power field, which correlates with infection. Bacterial vaginosis can be found by observing the diagnostic "clue" cells with microscopic examination of vaginal discharge.

Other Diagnostic Assessment

Abdominal ultrasonography may be used to determine the presence of appendicitis and tubo-ovarian abscesses that need to be ruled out when the diagnosis of PID is made. Transvaginal ultrasound and magnetic resonance imaging (MRI) are used in some cases to detect tubal wall thickening, fluid-filled tubes, and free pelvic fluid or a tubo-ovarian abscess, all associated with PID. Endometrial biopsy also has been used to increase the accuracy of the diagnosis.

ANALYSIS

The priority problem for patients with pelvic inflammatory disease (PID) is infection related to invasion of pelvic organs by pathogens.

PLANNING AND IMPLEMENTATION**Managing Infection**

Planning: Expected Outcomes. The patient with PID is expected to have her infection resolved and be free of abdominal pain.

Interventions. Patient-centered collaborative care includes antibiotic therapy, self-management measures, and surgical intervention (rarely).

Uncomplicated PID is usually treated on an ambulatory care basis. The CDC (2010d) recommends hospitalization for PID if the patient:

- Has appendicitis, ectopic pregnancy, or other surgical emergency that has not been excluded
- Is pregnant
- Does not respond to oral antibiotic therapy
- Is unable to follow or tolerate an outpatient regimen
- Has severe illness, nausea and vomiting, or high fever
- Has a tubo-ovarian abscess

There are no recommendations about whether HIV-infected women should be hospitalized. Assess the ability of high-risk women for self-management at home. The clinical patient's medical condition and availability of support systems are important considerations for home care. If the infection has not responded to treatment, the patient may need to be hospitalized for IV antibiotic therapy and further evaluation.

The CDC recommends oral and/or parenteral antibiotics for PID (CDC, 2010d). Drug therapy is required for 14 days.

If the woman has not responded to oral antibiotics, she is hospitalized for IV antibiotic therapy and further evaluation. Inpatient therapy involves a combination of several IV antibiotics until the woman shows signs of improvement (e.g., decreased pelvic tenderness for at least 24 hours). Then oral antibiotics are continued until the course of treatment has lasted 14 days.

Antibiotic therapy relieves pain by decreasing the inflammation caused by infection. Other pain relief measures include taking mild analgesics and applying heat to the lower abdomen or back. *Teach the patient to maintain rest in a semi-Fowler's position to promote gravity drainage of the infection that may help relieve pain.*

! NURSING SAFETY PRIORITY

Action Alert

Instruct women who are being treated for PID as outpatients to avoid sexual intercourse and to check their temperature twice a day. Teach them to report an increase in temperature to their health care provider. Remind them to be seen by the health care provider within 72 hours from starting the antibiotics and then 1 and 2 weeks from the time of the initial diagnosis.

In a small number of patients, the pain and tenderness may not be relieved by antibiotic therapy. The surgeon may perform a laparoscopy to remove an abscess through one or more sub-umbilical incisions to provide better access to the fallopian tubes. Before surgery, provide information about hospital routines and procedures. After surgery, the care of the woman with PID is similar to that of any patient after laparoscopic abdominal surgery. One difference is that she may have a wound drain for drainage of abscess fluid that may not have been completely removed during surgery. Observe, measure, and record wound drainage every 4 to 8 hours as requested.

Community-Based Care

Collaborate with the case manager or discharge planner before the woman is discharged to home. Teach the patient with PID to have regular follow-up with her health care provider to assess for complications and assess that the infection has resolved. The ongoing role of the nurse is to assess for any continued risk for contracting PID again, signs of persistent or recurrent infection, and education to prevent exposure to and infection with all STDs (e.g., decrease the number of partners, consistently use condoms). Establish an atmosphere of trust that encourages the woman to return frequently, if needed, for education or reassurance.

Home Care Management

Parenteral antibiotic therapy may be given at home, but usually the health care provider changes the treatment regimen to oral antibiotics before hospital discharge.

Teaching for Self-Management

Patient teaching focuses on providing information about PID, identifying recurrences (persistent pelvic pain, dysmenorrhea, low backache, fever), and urging early and complete self-management to prevent complications. Review information for oral antibiotic therapy (Chart 76-4).

Counsel the patient to contact her sexual partner(s) for examination and treatment. Partners should be treated for

CHART 76-4 PATIENT AND FAMILY EDUCATION: PREPARING FOR SELF-MANAGEMENT

Oral Antibiotic Therapy for Sexually Transmitted Diseases

- Take your medicine for the number of times a day it is prescribed and until it is completed.
- Your sexual partner must be treated if you have a sexually transmitted disease (STD). Expedited partner therapy is one way to ensure partners are treated.
- Be sure to return for your follow-up appointment after completing your antibiotic treatment.
- Call if you have any questions or concerns.
- Do not have sex until after you and your partner complete your antibiotic therapy. This should be at least 7 days, even if treatment is one dose.
- Drink at least 8 to 10 glasses of fluid a day while taking your antibiotics.
- Do not take antacids containing calcium, magnesium, or aluminum, such as Tums, Maalox, or Mylanta, with your antibiotics. They may decrease the effectiveness of the antibiotic.
- Take your antibiotics on an empty stomach unless your health care provider instructs you to take them with food.
- If you are taking oral contraceptives, you should discuss with your health care provider whether the antibiotics will decrease the effectiveness of your pills.

gonorrhea and chlamydia infection regardless of their lack of symptoms. Remind the patient about follow-up care, and counsel her about the complications that can occur after an episode of PID. These problems include increased risk for recurrence, ectopic pregnancy, and infertility. Chronic pelvic pain may also develop.

Discuss contraception and the patient's need or desire for it. This discussion includes methods that may decrease the risk for future episodes of PID, such as the use of barrier methods (e.g., condom). Help the patient understand lifestyle factors that increase the risk for recurrent episodes, including sexual intercourse with multiple partners. Douching has also been suggested as a risk behavior for development of PID and/or infection with *Chlamydia* or *N. gonorrhea*.

Psychosocial concerns may require teaching and counseling. A patient who has PID may exhibit a variety of feelings (guilt, disgust, anger) about having a condition that may have been transmitted to her sexually. These feelings may affect her relationship with significant others and future sexual relationships. She may also have concerns about future fertility if PID has damaged or scarred the fallopian tubes and other reproductive organs. Provide nonjudgmental emotional support, and allow time for the woman to discuss her feelings.

? NCLEX EXAMINATION CHALLENGE

Physiological Integrity

A client is being treated with oral antibiotics in the clinic for pelvic inflammatory disease. Which of these changes will the nurse teach the client to report immediately to the health care provider?

- Increased anxiety that her partner may "catch" the disease
- Mild nausea after taking some doses of the antibiotic
- One or two diarrheal stools every day since taking the antibiotic
- Temperature of 102° F after 3 days of taking the antibiotic

Health Care Resources

If infertility is a result of PID, the patient may need referral to a clinic specializing in infertility treatment and counseling. She can also contact support groups for infertile couples, which exist in many local communities.

The costs of antibiotics for care of patients with PID and other STDs may be a concern for those who are uninsured, underinsured, or impoverished. In collaboration with the case manager or social worker, help locate community resources for free or discounted drugs for women who cannot afford them. Ask the patient directly if she has money to pay for the drug therapy including her insurance co-pay, regardless of her apparent financial status.

EVALUATION: OUTCOMES

Evaluate the care of the patient with PID based on the identified priority patient problem. The expected outcomes include that the patient should:

- Show evidence that the infection has resolved
- Report or demonstrate that pain is relieved or reduced and that she feels more comfortable

VAGINAL INFECTIONS

Vaginal infection associated with sexual activity may produce vaginal discharge or vulvar irritation. The common causes of vaginal infection that can be but are not always sexually transmitted include:

- *Trichomonas vaginalis*
- *Candida*, primarily *C. albicans*
- Bacteria that produce bacterial vaginosis, including *Gardnerella vaginalis*, *Mycoplasma hominis* and anaerobes including *Prevotella* and *Mobiluncus* species

Men can also get these infections but are not always symptomatic.

Trichomoniasis and candida infections are limited to the vagina. They can be very irritating and bothersome but do not cause any long-term problems. The partner must also be treated for *trichomoniasis* if the infection is to be resolved. *Candidiasis* does not usually require partner treatment. However, if the male partner is symptomatic (irritation of the genital skin), treatment is indicated. It is important to remember that *Candida* is a normal flora on the skin and can easily be relocated to the vagina. Although it can be transmitted sexually, candidiasis occurs among women who are not sexually active. Also, antibiotics that change the normal flora of the vagina contribute to infection.

Bacterial vaginosis (BV) has been implicated in upper genital tract infections. Women undergoing surgery of the upper genital tract should be evaluated and treated if BV is found. [Chapter 74](#) describes the management of each of these infections.

OTHER SEXUALLY TRANSMITTED DISEASES

Less common diseases in the United States that are transmitted by sexual contact are lymphogranuloma venereum, chancroid, and granuloma inguinale. Like syphilis, all of these diseases are associated with ulcers but they are seen most often in less affluent countries. As newcomers migrate into the United States, these STDs may become more common. Ask patients suspected of these infections whether they have traveled out of the United States and whether they had sexual contact with people who live in other countries.

NURSING CONCEPT REVIEW

What might you NOTICE if the patient has altered sexuality as a result of a sexually transmitted disease (STD)?

- Report of heavy and abnormal vaginal discharge
- Report of urinary frequency or dysuria
- Ulcers, blisters, or warts in the genital area
- Low-grade fever
- Report of malaise
- Report of vaginal, penile, or anal itching or irritation
- Report of abdominal pain (pelvic inflammatory disease [PID])
- Anxious behavior

What should you INTERPRET and how should you RESPOND to a patient with altered sexuality as a result of STD?

Perform and interpret focused physical assessment, including:

- Vital signs
- Pain intensity and quality
- Skin inspection (genital area)

Respond by:

- Reporting and documenting all findings

- Helping patient with abdominal pain into a semi-Fowler's position
- Providing pain control measures
- Teaching patient about prescribed antibiotic or antiviral therapy
- Teaching patient to avoid sexual intercourse while being treated
- Teaching patient the importance of treating all sexual partners
- Teaching patient and partner(s) about safe sex practices
- Providing support and listening to the patient and partner(s) without judgment

On what should you REFLECT?

- Examine your feelings about patients who make sexual choices different from your own.
- Think about what else you could do to help patients meet their physical and emotional needs during this time.
- Determine what other health teaching may be needed for this patient.
- Monitor the patient's response to pain control interventions.

GET READY FOR THE NCLEX® EXAMINATION!**KEY POINTS**

Review these Key Points for each NCLEX Examination Client Needs Category.

Safe and Effective Care Environment

- Teach patients to not have sexual intercourse during their treatment for sexually transmitted disease (STD).
- Maintain patient and partner confidentiality and privacy at all times.
- Use gloves when examining the patient's genitalia or skin lesions.

Health Promotion and Maintenance

- Teach the patient about the availability of expedited partner treatment; be sure that all doses of the drug are taken by both the patient and the partner.
- Encourage all patients who are sexually active to use condoms during sexual intimacy (see [Chart 76-3](#)).
- Urge sexually active people, especially those younger than 25 years or those older than 25 years if at high risk, to have STD screenings at least annually.

Psychosocial Integrity

- Treat all patients, regardless of diagnosis, with respect.

- Provide privacy for patients undergoing examination or testing for STDs.
- Respect the sexual choices of all patients.
- Allow the patient the opportunity to express fear or anxiety regarding a diagnosis of STD.
- Refer patients newly diagnosed with an STD to local resources and support groups as needed based on their response.
- Encourage all patients who have an STD to inform their sexual partner(s) of their health status.

Physiological Integrity

- Encourage patients to adhere to their anti-infective drug regimen (see [Chart 76-4](#)).
- Teach patients the expected side effects and possible adverse reactions to prescribed drugs.
- Assess patients with STD using the guidelines in [Chart 76-1](#).
- Teach patients about the complications of STD using the information in [Table 76-2](#).
- Be aware that PID is diagnosed based on the criteria in [Table 76-4](#).

A

Do-Not-Use Abbreviations and Symbols

Symbol or Abbreviation	Intended Meaning	Potential Problem	Preferred Term
µg	Microgram	Mistaken as “mg” (milligram)	Use “mcg”
℥	Dram	Symbol for dram mistaken as “3”	Use the metric system
℥	Minim	Symbol for minim mistaken as “mL” (milliliter)	Use the metric system
@	At	Mistaken as “2”	Use “at”
&	And	Mistaken as “2”	Use “and”
+	Plus or and	Mistaken as “4”	Use “and”
°	Hour	Mistaken as a zero (e.g., q2° seen as “q20”)	Use “hr,” “h,” or “hour”
Ø	Zero, null sign	Mistaken as the numerals 4, 6, or 9	Use the number “0” or the word “zero”
i/d	One daily	Mistaken as “tid” (three times daily)	Use “1 daily”
/ (slash mark)	Separates two doses or indicates “per”	Mistaken as the number 1 (e.g., “25 units/10 units” misread as “25 units” and “110 units”)	Use “per” rather than a slash mark to separate doses
> and <	Greater than and less than	Mistaken as opposite of intended; mistakenly use incorrect symbol; “<10” mistaken as “40”	Use “greater than” or “less than”
AD, AS, AU	Right ear, left ear, each ear	Mistaken as OD, OS, OU (right eye, left eye, each eye)	Use “right ear,” “left ear,” or “each ear”
ARA A	vidarabine	Mistaken as cytarabine (ARA C)	Use complete drug name
AZT	zidovudine (Retrovir)	Mistaken as azathioprine or aztreonam	Use complete drug name
BT	Bedtime	Mistaken as “BID” (twice daily)	Use “bedtime”
cc	Cubic centimeter	Mistaken as “u” (unit)	Use “mL” (milliliter)
CPZ	Compazine (prochlorperazine)	Mistaken as chlorpromazine	Use complete drug name
D/C	Discharge or discontinue	Premature discontinuation of medications if D/C (intended to mean “discharge”) has been misinterpreted as “discontinued” when followed by a list of discharge medications	Use “discharge” and “discontinue”
DPT	Demerol-Phenergan-Thorazine	Mistaken as diphtheria-pertussis-tetanus (vaccine)	Use complete drug name
DTO	Diluted tincture of opium, or deodorized tincture of opium (Paregoric)	Mistaken as tincture of opium	Use complete drug name
HCl	hydrochloric acid or hydrochloride	Mistaken as potassium chloride (the “H” is misinterpreted as “K”)	Use complete drug name unless expressed as a salt of a drug
HCT	hydrocortisone	Mistaken as hydrochlorothiazide	Use complete drug name

Symbol or Abbreviation	Intended Meaning	Potential Problem	Preferred Term
HCTZ	hydrochlorothiazide	Mistaken as hydrocortisone (seen as HCT250 mg)	Use complete drug name
HS	Half-strength	Mistaken as bedtime	Use “half-strength” or “bedtime”
hs	At bedtime, hours of sleep	Mistaken as half-strength	Use “half-strength” or “bedtime”
IJ	Injection	Mistaken as “IV” or “intrajugular”	Use “injection”
IN	Intranasal	Mistaken as “IM” or “IV”	Use “intranasal” or “NAS”
IU	International unit	Mistaken as IV (intravenous) or 10 (ten)	Use “unit”
“IV Vanc”	Intravenous vancomycin	Mistaken as Invanz	Use complete drug name
MgSO ₄	Magnesium sulfate	Mistaken as morphine sulfate	Use complete drug name
MS, MSO ₄	Morphine sulfate	Mistaken as magnesium sulfate	Use complete drug name
MTX	methotrexate	Mistaken as mitoxantrone	Use complete drug name
“Nitro” drip	nitroglycerin infusion	Mistaken as sodium nitroprusside infusion	Use complete drug name
“Norflox”	norfloxacin	Mistaken as Norflex	Use complete drug name
OD, OS, OU	Right eye, left eye, each eye	Mistaken as AD, AS, AU (right ear, left ear, each ear)	Use “right eye,” “left eye,” or “each eye”
o.d. or OD	Once daily	Mistaken as “right eye” (OD—oculus dexter), leading to oral liquid medications administered in the eye	Use “daily”
OJ	Orange juice	Mistaken as OD or OS (right or left eye); drugs meant to be diluted in orange juice may be given in the eye	Use “orange juice”
PCA	procainamide	Mistaken as patient-controlled analgesia	Use complete drug name
Per os	By mouth, orally	The “os” can be mistaken as “left eye” (OS—oculus sinister)	Use “PO,” “by mouth,” or “orally”
PTU	propylthiouracil	Mistaken as mercaptopurine	Use complete drug name
q.d. or QD	Every day	Mistaken as q.i.d., especially if the period after the “q” or the tail of the “q” is misunderstood as an “i”	Use “daily”
qhs	Nightly at bedtime	Mistaken as “qhr” or every hour	Use “nightly”
qn	Nightly or at bedtime	Mistaken as “qh” (every hour)	Use “nightly” or “at bedtime”
q.o.d. or QOD	Every other day	Mistaken as “q.d.” (daily) or “q.i.d.” (four times daily) if the “o” is poorly written	Use “every other day”
q1d	Daily	Mistaken as q.i.d. (four times daily)	Use “daily”
q6PM, etc.	Every evening at 6 PM	Mistaken as every 6 hours	Use “daily at 6 PM” or “6 PM daily”
SC, SQ, sub q	Subcutaneous	SC mistaken as SL (sublingual); SQ mistaken as “5 every”; the “q” in “sub q” has been mistaken as “every” (e.g., a heparin dose ordered “sub q 2 hours before surgery” misunderstood as every 2 hours before surgery)	Use “subcut” or “subcutaneously”
ss	Sliding scale (insulin) or ½ (apothecary)	Mistaken as “55”	Spell out “sliding scale”; use “one-half” or “½”
SSRI	Sliding scale regular insulin	Mistaken as selective-serotonin reuptake inhibitor	Spell out “sliding scale (insulin)”
SSI	Sliding scale insulin	Mistaken as Strong Solution of Iodine (Lugol’s)	Spell out “sliding scale (insulin)”

Symbol or Abbreviation	Intended Meaning	Potential Problem	Preferred Term
T3	Tylenol with codeine No. 3	Mistaken as liothyronine	Use complete drug name
TAC	triamcinolone	Mistaken as tetracaine, Adrenalin, cocaine	Use complete drug name
TNK	TNKase	Mistaken as “TPA”	Use complete drug name
TIW or tiw	3 times a week	Mistaken as “3 times a day” or “twice in a week”	Use “3 times weekly”
U or u	Unit	Mistaken as the number 0 or 4, causing a tenfold overdose or greater (e.g., 4U seen as “40” or 4u seen as “44”); mistaken as “cc” so dose given in volume instead of units (e.g., 4u seen as “4cc”)	Use “unit”
×3d	For 3 days	Mistaken as “3 doses”	Use “for 3 days”
ZnSO ₄	zinc sulfate	Mistaken as morphine sulfate	Use complete drug name
Trailing zero after decimal point (e.g., 1.0 mg)	1 mg	Mistaken as 10 mg if the decimal point is missed	Do not use trailing zeroes for doses expressed in whole numbers
No leading zero before a decimal dose (e.g., .5 mg)	0.5 mg	Mistaken as 5 mg if the decimal point is not seen	Use zero before a decimal point when the dose is less than a whole unit
Drug name and dose run together (especially problematic for drug names that end in “l,” such as Inderal40 mg; Tegretol300 mg)	Inderal 40 mg Tegretol 300 mg	Mistaken as Inderal 140 mg Mistaken as Tegretol 1300 mg	Place adequate space between the drug name, dose, and unit of measure
Numerical dose and unit of measure run together (e.g., 10mg, 100mL)	10 mg 100 mL	The “m” is sometimes mistaken as a zero or two zeros, risking a 10- to 100-fold overdose	Place adequate space between the dose and unit of measure
Abbreviations such as mg. or mL. with a period after the abbreviation	mg mL	The period is unnecessary and could be mistaken as the number 1 if written poorly	Use mg, mL, etc. without a terminal period
Large doses without properly placed commas (e.g., 100000 units; 1000000 units)	100,000 units 1,000,000 units	100000 has been mistaken as “10,000” or “1,000,000”; 1000000 has been mistaken as “100,000”	Use commas for dosing units at or above 1,000, or use words such as 100 “thousand” or 1 “million” to improve readability

Data from Institute for Safe Medication Practices (www.ismp.org): ISMP's list of error-prone abbreviations, symbols, and dose designations, 2010; and The Joint Commission (www.jointcommission.org): The official “do not use” list, 2005.

Preliminary Examination

My name is ____, and I am your nurse.

I'm going to ...

take your vital signs.

weigh you.

take your blood pressure.

Extend your arm and relax.

Me llamo ____, y soy su enfermera(o).

Le voy a ...

tomar los signos vitales.

pesar.

tomar la presión.

Extienda su brazo y descánselo.

Meh YAH-moh ____, ee SOH-ee soo ehnh-fehr-MEH-rah(roh).

Leh VOH-ee ah ...

toh-MAHR lohs SEEG-nohs vee-TAH-lehs.

peh-SAHR.

toh-MAHR lah preh-see-OHN.

Ehks-tee-EHN-dah soo BRAH-soh ee dehs-KAHN-seh-loh.

Leh voy ah toh-MAHR ...

ehl POOL-soh.

soo tehnh-peh-rah-TOO-rah.

VOH-ee ah kohn-TAHR soos rehsh-pee-rah-see-OH-nehs.

I'm going to take your ...

pulse.

temperature.

I'm going to count your respirations.

Le voy a tomar ...

el pulso.

su temperatura.

Voy a contar sus respiraciones.

Obtaining a Blood Sample

I need to draw a blood sample.

Please give me your arm.

It may cause a little discomfort.

I am going to put a tourniquet around your arm.

I am going to draw blood from this vein.

Necesito tomar una muestra de la sangre.

Por favor, déme el brazo.

Le puede causar alguna molestia.

Le voy a poner una liga alrededor del brazo.

Voy a sacar la sangre de esta vena.

Neh-seh-SEE-toh toh-MAHR OO-nah moo-EHS-trah deh lah SAHN-greh.

Pohr fah-VOHR, DEH-meh ehl BRAH-soh.

Leh poo-EH-deh kah-OO-sahr ahl-GOO-nah moh-LEHS-tee-ah.

Leh VOH-ee ah poh-NEHR OO-nah LEE-gah ahl-reh-deh-DOHR dehl BRAH-soh.

VOH-ee ah sah-KAHR lah SAHN-greh deh EHS-tah VEH-nah.

Obtaining Blood from a Finger Stick

I need to take a few drops of blood from your finger.

Necesito sacar unas gotas de sangre de uno de sus dedos.

Neh-seh-SEE-toh sah-KAHR OO-nahs GOH-tahs deh SAHN-greh deh OO-noh deh soos DEH-dohs.

Obtaining a Urine Sample

We also need a urine sample.

También necesitamos una muestra de la orina.

Tahm-bee-EHN neh-seh-see-TAH-mohs OO-nah moo-EHS-trah deh lah oh-REE-nah.

It has to be from the middle of the stream.

Tiene que ser de la mitad del chorro.

Tee-EH-neh keh sehr deh lah mee-TAHD dehl CHOH-rroh.

Put the urine in this cup.

Ponga la orina en esta tasa.

POHN-gah lah oh-REE-nah ehn EHS-tah TAH-sah.

Obtaining a Stool Specimen

I need a sample of your stool.

Necesito una muestra de su excremento.

Neh-seh-SEE-toh OO-nah moo-EHS-trah deh soo ehks-kreh-MEN-toh.

Please put a small amount in this cup.

Por favor ponga un poco en esta tasa.

Pohr fa-VOHR POHN-gah oon POH-koh ehn EHS-tah TAH-sah.

Obtaining a Sputum Specimen

I need a sample of your sputum.

Necesito una muestra de su esputo.

Neh-seh-SEE-toh OO-nah MWEHS-trah deh soo ehs-POO-toh.

Please spit in this cup.

Por favor, escupa en este vaso.

throat is for breathing.

garganta es para respirar.

gahr-GAHN-tah ehs PAH-rah reh-pee-RAHR.

A

A delta fiber Myelinated fiber found primarily in the skin and muscle; carries rapid, sharp, pricking, or piercing sensations that can generally be localized to a well-defined area; also called “mechanical nociceptor.”

abdominoperineal (AP) resection The surgical removal of the sigmoid colon, rectum, and anus through combined abdominal and perineal incisions. This resection is performed when rectal tumors are present.

ablation The process or act of removing.

abscess A localized collection of pus caused by an inflammatory response to bacteria in tissues or organs.

absence seizure A type of generalized seizure consisting of brief periods of loss of consciousness and blank staring, as if daydreaming. The patient returns to baseline immediately after the seizure. This type is more common in children and tends to run in families. Left untreated, seizures may occur frequently throughout the day, interfering with daily life.

absolute neutrophil count (ANC) The percentage and actual number of mature circulating neutrophils; used to measure a patient’s risk for infection. The higher the numbers, the greater the resistance to infection.

absorbable suture A type of suture digested over time by body enzymes.

absorption The uptake from the intestinal lumen of nutrients produced by digestion.

abstinence syndrome Symptoms that occur when a patient who is physically dependent on opioids abruptly ceases using them. Slowly tapering (weaning) the drug dosage lessens or alleviates the physical withdrawal symptoms in a patient who is opioid dependent.

acalculia Difficulty with math calculations; caused by brain injury or disease.

acalculous cholecystitis Inflammation of the gallbladder occurring in the absence of gallstones; typically associated with biliary stasis caused by any condition that affects the regular filling or emptying of the gallbladder.

acceleration-deceleration Forces involved in high-speed crashes or falls from a great height; produce injury by tearing, shearing, and compressing anatomic structures.

acclimatization The process of adapting to a high altitude; involves physiologic changes that help the body compensate for less available oxygen in the atmosphere.

accommodation The process of maintaining a clear visual image when the gaze is shifted from a distant object to a near object. The eye adjusts its focus by changing the curvature of the lens.

achalasia An esophageal motility disorder believed to result from esophageal denervation; involves a failure to relax the smooth muscle fibers of the gastrointestinal tract and

characterized by chronic and progressive dysphagia. The term is typically used to refer to failure of the lower esophageal sphincter to relax properly with swallowing and to the replacement of normal peristalsis of the esophagus with abnormal contractions.

achlorhydria The absence of hydrochloric acid from gastric secretions.

acid A substance that releases hydrogen ions when dissolved in water. The strength of an acid is measured by how easily it releases hydrogen ions in solution.

acidosis An acid-base imbalance in which blood pH is below normal.

acinus The structural unit of the lower respiratory tract consisting of a respiratory bronchiole, an alveolar duct, and an alveolar sac.

Acorn cardiac support device A polyester mesh jacket that is placed over the ventricles to provide support and avoid overstretching the myocardial muscle in the patient with heart failure; reduces heart muscle hypertrophy and assists with improvement of ejection fraction.

acoustic neuroma A benign tumor of cranial nerve VIII; symptoms include damage to hearing, facial movements, and sensation. The tumor can enlarge into the brain, damaging structures in the cerebellum.

activated protein C An enzyme that helps prevent inappropriate clot formation. It is activated when it binds to healthy endothelial cells of the blood vessels; reduced levels are an indicator of sepsis and septic shock.

active euthanasia Purposeful action that directly causes death; not supported by most professional organizations, including the American Nurses Association.

active immunity Resistance to infection that occurs when the body responds to an invading antigen by making specific antibodies against the antigen. Immunity lasts for years and is natural by infection or artificial by stimulation (e.g., vaccine) of the body’s immune defenses.

activities of daily living (ADLs) The activities performed in the course of a normal day, such as bathing, dressing, feeding, and ambulating.

activity therapist A member of the rehabilitation health care team who works to help patients continue or develop hobbies or interests; also called “recreational therapist.”

acupoint One of the specific areas for acupressure and acupuncture located on meridians throughout the body.

acupressure A traditional Chinese medicine therapy in which the fingers are used to press certain points on the body to increase the flow of energy and promote the body’s self-healing ability.

acupuncture A traditional Chinese medicine therapy in which tiny needles are inserted into the skin and subcutaneous tissues at certain

areas of the body to deliver manual vibration or electrical stimulation.

acute Having relatively greater intensity; marked by a sudden onset and short duration.

acute adrenal insufficiency A life-threatening event in which the need for cortisol and aldosterone is greater than the available supply; also called “Addisonian crisis.”

acute arterial occlusion The sudden blockage of an artery, typically in the lower extremity, in the patient with chronic peripheral arterial disease.

acute compartment syndrome (ACS) A complication of a fracture characterized by increased pressure within one or more compartments and causing massive compromise of circulation to the area. Compartments are sheaths of inelastic fascia that support and partition muscles, blood vessels, and nerves in the body.

acute coronary syndrome (ACS) A disorder, including unstable angina and myocardial infarction, that results from obstruction of the coronary artery by ruptured atherosclerotic plaque and leads to platelet aggregation, thrombus formation, and vasoconstriction.

acute gastritis Inflammation of the gastric mucosa or submucosa after exposure to local irritants. Various degrees of mucosal necrosis and inflammatory reaction occur in acute disease. Complete regeneration and healing usually occur within a few days.

acute hematogenous infection An infection resulting from bacteremia, disease, or nonpenetrating trauma that is disseminated by the blood through the circulation.

acute ischemic stroke (AIS) A stroke caused by the occlusion (blockage) of a cerebral artery by either a thrombus or an embolus.

acute kidney failure A rapid decrease in kidney function that leads to the accumulation of metabolic wastes in the body. It is caused by inadequate kidney perfusion; damage to the glomeruli, interstitial tissue, or tubules; or obstructed urine flow. It can progress to end-stage kidney disease in patients with chronic renal insufficiency.

acute kidney injury A rapid decrease in kidney function, leading to the collection of metabolic wastes in the body; formerly called “acute renal failure (ARF).”

acute pain The unpleasant sensory and emotional experience associated with tissue damage that results from acute injury, disease, or surgery.

acute pancreatitis A serious inflammation of the pancreas characterized by a sudden onset of abdominal pain, nausea, and vomiting. It is caused by premature activation of pancreatic enzymes that destroy ductal tissue and pancreatic cells and results in autodigestion and fibrosis of the pancreas.

acute paronychia Inflammation of the skin around the nail, which usually occurs with a torn cuticle or an ingrown toenail.

acute pericarditis An inflammation or alteration of the pericardium, the membranous sac that encloses the heart; may be fibrous, serous, hemorrhagic, purulent, or neoplastic.

acute pyelonephritis Active bacterial infection in the kidney.

acute respiratory distress syndrome (ARDS) Respiratory failure marked by hypoxemia that persists even when 100% oxygen is given, as well as decreased pulmonary compliance, dyspnea, noncardiac-associated bilateral pulmonary edema, and dense pulmonary infiltrates on x-ray.

acute sialadenitis Inflammation of a salivary gland; can be caused by infectious agents, irradiation, or immunologic disorders.

adaptive immunity The immunity that a person's body makes (or can receive) as an adaptive response to invasion by organisms or foreign proteins; occurs either naturally or artificially through lymphocyte responses and can be either active or passive.

adaptive mechanism The means of producing compensation; also called "compensatory mechanism."

addiction A primary, chronic neurobiologic disease characterized by impaired control over drug use, compulsive use, continued use despite harm, and craving.

adisonian crisis Acute adrenal insufficiency; a life-threatening event in which the need for cortisol and aldosterone is greater than the available supply.

additive In pharmacology, a drug that adds an effect, either harmful or beneficial, when given with another drug.

adenocarcinoma Tumor that arises from the glandular epithelial tissue.

adenohypophysis The anterior lobe of the pituitary gland, which makes up about 70% of the gland.

adiponectin An anti-inflammatory and insulin sensitizing hormone.

adipose Fatty.

adjuvant A substance that aids another substance, such as a cancer treatment that uses chemotherapy in addition to surgery.

adjuvant drug Drug used to relieve pain either alone or in combination with an analgesic to enhance the effectiveness of the analgesic.

adjuvant therapy Chemotherapy that is used along with surgery or radiation.

adrenal crisis Acute adrenocortical insufficiency, which can be life threatening.

adrenal Cushing's disease An excess of glucocorticoids caused by a problem in the adrenal cortex, usually a benign tumor (adrenal adenoma). This usually occurs in only one adrenal gland.

adrenal steroid Any of the hormones produced and secreted by the adrenal cortex; also called "corticosteroid."

advance directive A written document prepared by a competent person to specify what,

if any, extraordinary actions he or she would want when no longer able to make decisions about personal health care.

adverse drug event (ADE) An unintended harmful reaction to an administered drug.

aerophagia The excessive swallowing of air.

aerosolization Transmission via fine airborne droplets.

aesthetic plastic surgery Plastic surgery that is cosmetic and aims to alter a person's physical appearance.

afferent arteriole The smallest, most distal portion of the renal arterial system that supplies blood to the nephron. From the afferent arteriole, blood flows into the glomerulus, a series of specialized capillary loops.

afferent loop syndrome Chronic partial obstruction of the duodenal loop after partial gastrectomy and gastrojejunostomy, resulting in abdominal bloating and pain after eating; often followed by nausea and vomiting.

after-drop A continued decrease in core body temperature after a victim is removed from a cold environment; results from equilibration of core and peripheral blood temperature and counter-current cooling of the blood perfusing cold tissue.

afterload The pressure or resistance that the ventricles must overcome to eject blood through the semilunar valves and into the peripheral blood vessels; the amount of resistance is directly related to arterial blood pressure and blood vessel diameter.

agglutination A clumping action that results during the antibody-binding process when antibodies link antigens together to form large and small immune complexes.

aggregation Clumping together.

agnosia A general term for a loss of sensory comprehension; may include an inability to write, comprehend reading material, or use an object correctly.

agraphia Loss of the ability to write; caused by brain injury or disease.

Airborne Precautions Infection control guidelines from the Centers for Disease Control and Prevention; used for patients with infections spread by the airborne transmission route, such as tuberculosis. Negative airflow rooms are required to prevent the airborne spread of microbes.

akinesia Slow or no movement, as seen in a patient with Parkinson disease; also called "bradykinesia."

alanine aminotransferase (ALT) An enzyme found in the liver. Levels of this enzyme are elevated in patients with liver disease, infectious mononucleosis, and other disorders.

albuminuria The presence of albumin in the urine.

alcohol abuse A condition in which a person has problems related to alcohol use but does not have a strong craving for alcohol, loss of control, or physical dependence.

alcoholic hepatitis Liver inflammation caused by the toxic effect of alcohol on hepatocytes. The liver becomes enlarged, with cellular

degeneration and infiltration by fat, leukocytes, and lymphocytes.

alcoholism A disease in which a person has a strong need or compulsion to consume alcohol, is unable to quit once he or she begins drinking, experiences a physical dependence, and needs to increase the amount of alcohol to get "high."

aldosterone The chief mineralocorticoid produced by the adrenal cortex. Aldosterone increases kidney reabsorption of sodium and water, thus restoring blood pressure, blood volume, and blood sodium levels. Aldosterone secretion is regulated by the renin-angiotensin system, serum potassium ion concentration, and adrenocorticotrophic hormone.

alert Awake and responsive to stimulation.

alexia Problems understanding written language; caused by brain injury or disease.

alkaline reflux gastropathy A complication of gastric surgery in which the pylorus is bypassed or removed. Endoscopic examination reveals regurgitated bile in the stomach and mucosal hyperemia. Symptoms include early satiety, abdominal discomfort, and vomiting; also called "bile reflux gastropathy."

alkalosis An acid-base imbalance in which blood pH is above normal.

allele An alternate form (or variation) of a gene.

allergen A foreign protein that is capable of causing a hypersensitivity response, or allergy, that ranges from uncomfortable (itchy, watery eyes or sneezing) to life threatening (allergic asthma, anaphylaxis, bronchoconstriction, or circulatory collapse); causes a release of natural chemicals, such as histamine, in the body.

allergy An increased or excessive response to the presence of a foreign protein or allergen (antigen) to which the patient has been previously exposed.

allogenic Having cell types that are antigenically distinct; for example, bone marrow transplantation in which the patient receives bone marrow or peripheral blood taken from a healthy donor. Compare with autologous bone marrow transplantation, in which patients receive their own cells, which were collected earlier.

allogenic bone marrow transplantation The transplantation of bone marrow from a sibling.

allogenic transplant Type of bone marrow transplant in which a closely HLA-matched sibling or an unrelated but matched donor provides the stem cells.

allograft A graft of tissue or bone between individuals of the same species but a different genotype; the donor may be a cadaver or a living person, either related or unrelated; also called "homograft."

alopecia Hair loss.

alveolitis Inflammation of the alveoli.

Alzheimer's disease (AD) A chronic, progressive, degenerative disease that accounts for 60% of the dementias occurring in people older than 65 years; characterized by loss of

- memory, judgment, and visuospatial perception and by a change in personality. Over time, the patient becomes increasingly cognitively impaired. Severe physical deterioration takes place, and death occurs as a result of complications of immobility; also called “dementia, Alzheimer type.”
- amaurosis fugax** A transient, brief episode of blindness in one eye.
- ambulatory** A term that refers to a patient who goes to the hospital or physician's office and returns home on the same day.
- ambulatory aid** Assistive device such as a cane or a walker.
- ambulatory pump** Infusion therapy pump generally used with a home care patient to allow a return to his or her usual activities while receiving infusion therapy.
- amebic hepatic abscess** A liver abscess caused by the protozoan *Entamoeba histolytica*; may occur after amebic dysentery and usually occurs as a single abscess in the right hepatic lobe.
- amenorrhea** The absence of menstrual periods in women.
- amnesia** Loss of memory.
- amputation** The removal of a limb or other appendage of the body.
- amyotrophic lateral sclerosis (ALS)** A progressive and degenerative disease of the motor system that is characterized by atrophy of the hands, forearms, and legs and results in paralysis and death. There is no known cause, no cure, no specific treatment, no standard pattern of progression, and no method of prevention; also called “Lou Gehrig's disease.”
- anabolic hormone** A hormone that stimulates growth.
- anabolic steroids** Synthetic substances that mimic the actions of testosterone. Prescribed for people with hormonal difficulties such as delayed puberty or impotence and misused by athletes to increase strength and performance.
- anaerobic** Lacking adequate oxygen.
- anaerobic cellular metabolism** Metabolism without oxygen.
- anal fissure** A painful ulcer at the margin of the anus.
- analgesia** Pain relief or pain suppression.
- analgesia team** Team typically consisting of one or more nurses, pharmacists, case managers, and physicians who consult with staff and prescribers on how best to control the patient's pain; also called “multidisciplinary pain team.”
- anaphylaxis** The widespread reaction that occurs in response to contact with a substance to which the person has a severe allergy (antigen); characterized by blood vessel and bronchiolar smooth muscle involvement causing widespread blood vessel dilation, decreased cardiac output, and bronchoconstriction; results in cell damage and the release of large amounts of histamine, severe hypovolemia, vascular collapse, decreased cardiac contraction, and dysrhythmias and causes extreme whole-body hypoxia.
- anasarca** Generalized edema.
- anastomosis** Surgical reattachment; also a general term meaning a connection.
- anatomic dead space** Places in which air flows but the structures are too thick for gas exchange.
- androgen** Any substance, such as testosterone, that promotes masculinization; male hormones.
- anemia** A clinical sign of some abnormal condition related to a reduction in one of the following: number of red blood cells, amount of hemoglobin, or hematocrit (percentage of packed red blood cells per deciliter of blood).
- anergy** The inability to mount an immune response to an antigen.
- anesthesia** An induced state of partial or total loss of sensation with or without loss of consciousness.
- anesthetic** Agent that produces loss of sensation.
- aneuploid** An abnormal karyotype with more or fewer than 23 pairs of chromosomes.
- aneurysm** A permanent localized dilation of an artery (to at least two times its normal diameter) that forms when the middle layer (media) of the artery is weakened, stretching the inner (intima) and outer (adventitia) layers. As the artery widens, tension in the wall increases and further widening occurs, thus enlarging the aneurysm.
- aneurysmectomy** A surgical procedure performed to excise an aneurysm.
- angina pectoris** Literally, “strangling of the chest”; a temporary imbalance between the ability of the coronary arteries to supply oxygen and the demand for oxygen by the cardiac muscle. As a result, the patient experiences chest discomfort.
- angioedema** Diffuse swelling resulting from a vascular reaction in the deep tissues; can occur in a patient having an anaphylactic reaction.
- anion** Ion that has a negative charge.
- anisocoria** A difference in the size of the pupils.
- ankle-brachial index (ABI)** A ratio derived by dividing the ankle blood pressure by the brachial blood pressure; this calculation is used to assess the vascular status of the lower extremities. To obtain the ABI, a blood pressure cuff is applied to the lower extremities just above the malleoli. The systolic pressure is measured by Doppler ultrasound at both the dorsalis pedis and posterior tibial pulses. The higher of these two pressures is then divided by the higher of the two brachial pulses.
- ankylosing spondylitis** A form of rheumatoid arthritis that affects the vertebral column and causes spinal deformities.
- anomia** Inability to find words.
- anorectal abscess** A localized induration and fluctuance that is caused by inflammation of the soft tissue near the rectum or anus and is most often the result of obstruction of the ducts of glands in the anorectal region by feces, foreign bodies, or trauma.
- anorectic drugs** Drugs that suppress appetite, which reduces food intake and, over time, may result in weight loss; may be prescribed for obese patients in a comprehensive weight reduction program.
- anorexia** The loss of appetite for food.
- anorexia nervosa** An eating disorder of self-induced starvation resulting from a fear of fatness, even though the patient is underweight.
- anorexin** Neuropeptide that decreases appetite.
- anoxic** Completely lacking oxygen.
- antalgic gait** A term that refers to an abnormality in the stance phase of gait. When part of one leg is painful, the person shortens the stance phase on the affected side.
- anterior colporrhaphy** Surgery for severe symptoms of cystocele in which the pelvic muscles are tightened for better bladder support.
- anterior cord syndrome** A condition caused by cervical injuries; results from damage to the anterior portion of both the gray and white matter of the spinal cord, usually as a result of decreased blood supply. Motor function and pain and temperature sensation are lost below the level of injury, but the sensations of touch, position, and vibration remain intact.
- anterior nares** The nostrils or external openings into the nasal cavities.
- antibody-mediated immune system** The defense response that produces antibodies directed against certain pathogens. The antibodies inactivate the pathogens and protect against future infection from that microorganism.
- anticoagulant** Something that limits blood clot formation.
- antidepressants** A group of drugs that help manage clinical depression.
- antiepileptic drugs (AEDs)** A class of drugs used to control seizures; also called “anticonvulsants.”
- antigen** A foreign protein or allergen that is capable of causing an immune response; protein on the surface of a cell.
- antiplatelet agents** Drugs that destroy blood platelets.
- anuria** Complete lack of urine output; usually defined as less than 100 mL/24 hr.
- anuric** Characterized by anuria (complete lack of urine output).
- aortic regurgitation** The flow of blood from the aorta back into the left ventricle during diastole; occurs when the aortic valve leaflets do not close properly during diastole and the annulus (the valve ring that attaches to the leaflets) is dilated or deformed.
- aortic stenosis** Narrowing of the aortic valve orifice and obstruction of left ventricular outflow during systole.
- aortic valve** The semilunar valve of the heart that separates the left ventricle from the aorta.
- aphasia** Inability to use or comprehend spoken or written language due to brain injury or disease.
- aphonia** Inability to produce sound; complete but temporary loss of the voice.
- aphthous stomatitis** Noninfectious stomatitis.

apical impulse The pulse located at the left fifth intercostal space in the midclavicular line in the mitral area (the apex of the heart); also called the “point of maximal impulse.”

aplastic anemia A deficiency of circulating red blood cells because of failure of the bone marrow to produce these cells; usually occurs with leukopenia and thrombocytopenia.

apolipoprotein E One of several regulators of lipoprotein metabolism.

apoptosis Programmed cell death that occurs when deoxyribonucleic acid in the telomere is gone and the chromosomes unravel.

appendectomy Surgical removal of the inflamed appendix.

appendicitis Acute inflammation of the vermiform appendix, which is the blind pouch attached to the cecum of the colon, which is usually located in the right iliac region just below the ileocecal valve.

approximated In a clean laceration or a surgical incision to be closed with sutures or staples, the act of bringing together the wound edges with the skin layers lined up in correct anatomic position so they can be held in place until healing is complete.

apraxia The loss of the ability to carry out a purposeful motor activity.

aqueous humor The clear, watery fluid that is continually produced by the ciliary processes and fills the anterior and posterior chambers of the eye. This fluid drains through the canal of Schlemm into the blood to maintain balanced intraocular pressure (pressure within the eye).

arcus senilis An opaque ring within the outer edge of the cornea caused by fat deposits. Its presence does not affect vision.

areflexic bladder Urinary retention and overflow (dribbling) caused by injuries to the lower motor neuron at the spinal cord level of S2 to S4 (e.g., multiple sclerosis and spinal cord injury below T12). Bladder emptying may be achieved by performing a Valsalva maneuver or tightening the abdominal muscles. The effectiveness of these maneuvers should be ascertained by catheterizing the patient for residual urine after voiding. Also called “flaccid bladder.”

aromatherapy A complementary therapy that uses essential oils obtained from plants to enhance psychological and physical well-being; may be applied in compresses, used in baths, or applied topically to the skin.

arrhythmogenic right ventricular cardiomyopathy (dysplasia) A form of cardiomyopathy that results from the replacement of myocardial tissue with fibrous and fatty tissue.

arterial revascularization The surgical procedure most commonly used to increase arterial blood flow in the affected limb of a patient with peripheral arterial disease.

arterial ulcers A painful complication in the patient with peripheral arterial disease. Typically, the ulcer is small and round, with a “punched out” appearance and well-defined borders. Ulcers develop on the toes (often the great toe), between the toes, or on the upper

aspect of the foot. With prolonged occlusion, the toes can become gangrenous.

arteriography Angiography of the arterial vessels; this invasive diagnostic procedure involves fluoroscopy and the use of a contrast medium and is performed when an arterial obstruction, narrowing, or aneurysm is suspected.

arteriosclerosis A thickening, or hardening, of the arterial wall.

arteriotomy A surgical opening into an artery.

arteriovenous malformation (AVM) An abnormality that occurs during embryonic development, resulting in a tangled mass of malformed, thin-walled, dilated vessels. The congenital absence of a capillary network in these vessels forms an abnormal communication between the arterial and venous systems and increases the risk that the vessels may rupture, causing bleeding into the subarachnoid space or into the intracerebral tissue. In the absence of the capillary network, the thin-walled veins are subjected to arterial pressure.

arteritis Inflammation of arterial walls.

arthralgia Pain in a joint.

arthritis Inflammation of one or more joints.

arthrodesis The surgical fusion of a joint.

arthrogram An x-ray study of a joint after contrast medium (air or solution) has been injected to enhance its visualization.

arthroscopy Examination of the interior of a joint with an arthroscope (a fiberoptic tube).

articulations Joint surfaces.

artifact In the electrocardiogram, interference that is seen on the monitor or rhythm strip and may look like a wandering or fuzzy baseline; can be caused by patient movement, loose or defective electrodes, improper grounding, or faulty equipment.

ascending paralysis Paralysis that begins in the legs and spreads to the arms and upper body.

ascending tracts Groups of nerves that originate in the spinal cord and end in the brain.

ascites The accumulation of free fluid within the peritoneal cavity. Increased hydrostatic pressure from portal hypertension causes this fluid to leak into the peritoneal cavity.

aseptic meningitis A type of meningitis that often occurs after viral illnesses such as measles, herpes simplex, coxsackievirus, and echovirus and is marked by inflammation over the cerebral cortex, white matter, and meninges. The formation of exudate (common in bacterial meningitis) does not occur, and no organisms are obtained from the cerebrospinal fluid. Also called “viral meningitis.”

aseptic necrosis See *avascular necrosis (AVN)*.

ASKED Model of Cultural Competence created by Dr. Josie Campinha-Bacote that provides a beginning self-assessment tool for cultural competence.

aspartate aminotransferase (AST) An enzyme found in the liver. Levels of this enzyme are elevated in patients with liver disorders and are highest in conditions that cause necrosis, such as severe viral hepatitis.

assistive/adaptive device Any item that enables the patient to perform all or part of an activity independently.

asterixis A coarse tremor characterized by rapid, nonrhythmic extensions and flexions in the wrists and fingers; a motor disturbance seen in portal-systemic encephalopathy; also called a “liver flap” or “flapping tremor.”

astigmatism A refractive error caused by unevenly curved surfaces on or in the eye (especially of the cornea) that distort vision.

asynchronous (fixed-rate) pacing mode

The mode of temporary cardiac pacing in which the pulse generator does not sense any intrinsic beats of the patient but fires at a fixed rate, regardless of the intrinsic rhythm. Used when the patient is asystolic or profoundly bradycardic, as may occur after open-heart surgery.

ataxia Gait disturbance or loss of balance.

atelectasis Collapse of alveoli.

atherectomy An invasive nonsurgical technique in which a high-speed, rotating metal burr uses fine abrasive bits to scrape plaque from inside an artery while minimizing damage to the vessel surface.

atherosclerosis A type of arteriosclerosis that involves the formation of plaque within the arterial wall; the leading contributor to coronary artery and cerebrovascular disease.

atonic (akinetic) seizure A type of generalized seizure characterized by a sudden loss of muscle tone that lasts for seconds and is followed by postictal confusion. These seizures usually cause the patient to fall, which may result in injury.

atresia Congenital absence of a normal body orifice or tubular organ, such as the ear canal.

atrial fibrillation (AF) A cardiac dysrhythmia in which multiple rapid impulses from many atrial foci, at a rate of 350 to 600 times per minute, depolarize the atria in a totally disorganized manner, with no P waves, no atrial contractions, a loss of the atrial kick, and an irregular ventricular response.

atrial flutter A cardiac dysrhythmia that involves rapid atrial depolarization and occurs at a rate of 250 to 350 times per minute.

atrial gallop An abnormal fourth heart sound that occurs as blood enters the ventricles during the active filling phase at the end of ventricular diastole; may be heard in patients with hypertension, anemia, ventricular hypertrophy, myocardial infarction, aortic or pulmonic stenosis, and pulmonary emboli.

atrial overdrive pacing A type of pacing that may be used to terminate symptomatic tachydysrhythmias such as atrial flutter or atrial fibrillation. Overdrive pacing is accomplished by rapidly pacing the atrium to capture the heart and control depolarization and is followed by no pacing in the hope that the sinus node will regain control of the heart.

atrioventricular (AV) block The delay or blockage of supraventricular impulses in the

atrioventricular node or intraventricular conduction system; usually classified as first-, second-, or third-degree block. Conduction may be transiently or permanently abnormal.

atrioventricular (AV) junction In the cardiac conduction system, the area consisting of a transitional cell zone, the atrioventricular (AV) node itself, and the bundle of His. The AV node lies just beneath the right atrial endocardium, between the tricuspid valve and the ostium of the coronary sinus.

at-risk drinking Drinking behavior in which five or more alcoholic beverages for men (four or more for women) are consumed.

atrophic gastritis A type of chronic gastritis that is seen most often in older adults. It can occur after exposure to toxic substances in the workplace (e.g., benzene, lead, and nickel) or *Helicobacter pylori* infection, or it can be related to autoimmune factors.

attenuated The quality of making a substance weaker; for example, antigens that are used to make vaccines are specially processed to make them less likely to grow in the body.

atypical angina Angina that manifests itself as indigestion, pain between the shoulders, an aching jaw, or a choking sensation that occurs with exertion. Many women experience atypical angina.

atypical migraine The least common of the three types of migraine headaches, after migraines with aura and migraines without aura; the atypical category includes menstrual and cluster migraines.

audiogram The graphic record of the results of pure-tone audiometry.

audiometer An electronic device that produces pure tones at various frequencies; used in determining hearing acuity.

aura A sensation that signals the onset of a headache or seizure; the patient may experience visual changes, flashing lights, or double vision.

autoamputation of the distal digits A condition in which the tips of the digits fall off spontaneously; can occur in severe cases of Raynaud's phenomenon.

autoantibodies Antibodies directed against self tissues of cells.

autocontamination The occurrence of infection in which the patient's own normal flora overgrows and penetrates the internal environment.

autodigestion Self-digestion. Specifically, the process of the stomach digesting itself if there is a break in its protective mucosal barrier.

autoimmune pancreatitis A chronic inflammatory form of pancreatitis that can also affect the bile ducts, kidneys, and other major connective tissues.

autologous blood transfusion Reinfusing the patient's own blood during surgery.

autologous donation The donation of a patient's own blood before scheduled surgery for use, if needed, during the surgery to eliminate transfusion reactions and reduce the risk of bloodborne disease.

autologous transplant A type of bone marrow transplant in which patients receive their own stem cells, which were collected before high-dose therapy.

autolysis The spontaneous disintegration of tissue by the action of the patient's own cellular enzymes.

automaticity The ability of a cell to initiate an impulse spontaneously and repetitively; in cardiac electrophysiology, the ability of primary pacemaker cells (SA node, AV junction) to generate an electrical impulse.

automatism Behavior of which the patient is not aware and which is not under the patient's control, such as lip smacking or picking at clothes; occurs in some types of seizure disorders.

autonomic dysreflexia A syndrome that affects the patient with an upper spinal cord injury; characterized by severe hypertension and headache, bradycardia, nasal stuffiness, and flushing; caused by a noxious stimulus, usually a distended bladder or constipation. This is a neurologic emergency and must be promptly treated to prevent a hypertensive brain attack.

autonomic nervous system (ANS) The part of the nervous system that is not under conscious control; consists of the sympathetic nervous system and the parasympathetic nervous system.

autoregulation The tendency of an organ or system to maintain blood flow at a fairly constant rate by dilating or constricting arteries in response to changes in blood pressure, carbon dioxide tension, and oxygen tension.

autosome Any of the 22 pairs of human chromosomes containing genes that code for all the structures and regulatory proteins needed for normal function but do not code for the sexual differentiation of a person.

avascular Lacking a blood supply.

avascular necrosis (AVN) The death of bone tissue, usually because the blood supply to the bone is disrupted. It is usually a complication of a hip fracture or any fracture in which there is displacement of bone; also called "osteonecrosis."

axial loading A mechanism of injury that involves vertical compression. An example is a diving accident, in which the blow to the top of the head causes the vertebrae to shatter and pieces of bone enter the spinal canal and damage the cord.

azoospermia The absence of living sperm in the semen.

azotemia An excess of nitrogenous wastes (urea) in the blood.

B

B-type natriuretic peptide (BNP) A peptide produced and released by the ventricles when the patient has fluid overload as a result of heart failure (HF).

Babinski's sign Dorsiflexion of the great toe and fanning of the other toes, which is an abnormal reflex in response to testing the plantar reflex with a pointed (but not sharp)

object; indicates the presence of central nervous system disease. The normal response is plantar flexion of all toes.

bacteremia The presence of bacteria in the bloodstream.

bacteriuria Bacteria in the urine.

bad death A death embodied by pain, not having one's wishes followed at the end of one's life, isolation, abandonment, and constant agonizing about losses associated with death.

Baker's cyst Enlarged popliteal bursa.

balanced analgesia See *multimodal analgesia*.

balanitis circinata Ringlike inflammation of the glans penis.

Ballance's sign During percussion, resonance over the right flank with the patient lying on the left side; this is an abnormal sign associated with abdominal trauma and is found with a ruptured spleen.

ballottement A maneuver to detect fluid in the knee by grasping the medial and lateral aspect of the knee between the thumb and third finger and pushing down on the top surface of the patella with the forefinger. If fluid is present, the patella can be pressed down a distance and rises back up when the forefinger is removed.

banding See *endoscopic variceal ligation*.

barbiturate coma The use of drugs such as pentobarbital sodium or sodium thiopental at dosages to maintain complete unresponsiveness; used for patients whose increased intracranial pressure cannot be controlled by other means. These drugs decrease the metabolic demands of the brain and cerebral blood flow, stabilize cell membranes, decrease the formation of vasogenic edema, and produce a more uniform blood supply. The patient in a barbiturate coma requires mechanical ventilation, sophisticated hemodynamic monitoring, and intracranial pressure monitoring.

bariatrics Branch of medicine that manages obesity and its related diseases.

barium enema See *lower GI series*.

baroreceptors Sensory receptors in the arch of the aorta and at the origin of the internal carotid arteries that are stimulated when the arterial walls are stretched by an increased blood pressure.

barotrauma An injury caused by rapid changes of pressure; usually refers to injury to the eardrum caused by an increase in pressure within the middle ear or to lung damage from excessive pressure.

Barrett's epithelium Columnar epithelium (instead of the normal squamous cell epithelium) that develops in the lower esophagus during the process of healing from gastroesophageal reflux disease. It is considered premalignant and is associated with an increased risk of cancer in patients with prolonged disease.

Barrett's esophagus Ulceration of the lower esophagus caused by exposure to acid and pepsin, leading to the replacement of normal

distal squamous mucosa with columnar epithelium as a response to tissue injury.

basal insulin secretion The low levels of insulin that are secreted during fasting.

basal rate A type of regimen for continuous infusion of patient-controlled analgesia that provides more consistent analgesia.

base A substance that binds (reduces) free hydrogen ions in solution. Strong bases bind hydrogen ions easily; weak bases bind less readily.

Bell's palsy Acute paralysis of cranial nerve VII; characterized by a drawing sensation and paralysis of all facial muscles on the affected side. The patient cannot close the eye, wrinkle the forehead, smile, whistle, or grimace. The face appears masklike and sags; also called "facial paralysis."

beneficence The ethical principle of preventing harm and ensuring the patient's well-being.

benign Altered cell growth that is harmless and does not require intervention.

benign prostatic hyperplasia (BPH) Age-associated enlargement of the prostate gland in men, which may cause bladder compression and can obstruct urinary flow.

benign tumor cells Normal cells growing in the wrong place or at the wrong time.

bereavement Grief and mourning experienced by the survivor before and after a death.

bicaval technique Surgical technique in heart transplantation in which the intact right atrium of the donor heart is preserved by anastomoses at the recipient's superior and inferior vena cavae.

bifurcation The point of division of a single structure into two branches.

bigeminy A type of premature complex that exists when normal complexes and premature complexes occur alternately in a repetitive two-beat pattern, with a pause occurring after each premature complex so that complexes occur in pairs.

bilateral orchiectomy The surgical removal of both testes, typically performed as palliative surgery in patients with prostate cancer. It is not intended to cure the prostate cancer but to arrest its spread by removing testosterone.

bilateral salpingo-oophorectomy (BSO) Surgical removal of both fallopian tubes and both ovaries.

biliary colic Intense pain due to obstruction of the cystic duct of the gallbladder from a stone moving through or lodged within the duct. Tissue spasm occurs in an effort to mobilize the stone through the small duct.

biliary stent A plastic or metal device that is placed percutaneously to keep a duct of the biliary system open in patients experiencing biliary obstruction.

biofilm A complex group of microorganisms that functions within a "slimy" gel coating on medical devices.

biological response modifiers (BRMs) A class of immunomodulating drugs that attempt to modify the course of disease.

biologically based therapies Therapies that use natural substances for healing, including herbs, foods, vitamins, and minerals.

bivalve To cut a cast lengthwise into two equal pieces.

black box warning A governmental designation indicating that a drug has at least one serious side effect and must be used with caution.

bladder ultrasound Less invasive test to determine postvoiding residual urine volumes for the patient with a reflex (upper motor neuron) or uninhibited bladder; often used to measure residual urine in the bladder of patients with spinal cord injury.

blanch To whiten.

blast effect Injury resulting from impact forces such as that of an exploding bomb.

blast phase cell Immature cell that divides.

blepharitis An inflammation of the eyelid edges.

bloodborne metastasis The release of tumor cells into the blood; the most common cause of cancer spread.

blood pressure (BP) The force of blood exerted against the vessel walls.

Blumberg's sign Pain felt on abrupt release of steady pressure (rebound tenderness) over the site of abdominal pain.

blunt trauma Injury resulting from impact forces such as those sustained in a motor vehicle crash or a fall.

body mass index (BMI) A measure of nutritional status that does not depend on frame size; indirectly estimates total fat stores within the body by the relationship of weight to height.

bolus feeding A method of tube feeding that involves intermittent feeding of a specified amount of enteral product at specified times during a 24-hour period, typically every 4 hours.

bone mineral density (BMD) The quality of bone that determines bone strength. It peaks between 30 and 35 years of age, when both bone resorption activity and bone-building activity occur at a constant rate. When bone resorption activity exceeds bone-building activity, bone density decreases.

bone remodeling The process of bone tissue constantly undergoing change.

bone resorption Loss of bone density due to demineralization resulting from the release of calcium from storage areas in bones.

bone scan A radionuclide test in which radioactive material is injected for visualization of the entire skeleton; used to detect tumors, arthritis, osteomyelitis, osteoporosis, vertebral compression fractures, and unexplained bone pain.

bony ossicle Small bone; in the ear, the malleus, the incus, and the stapes, which are found in the epitympanum.

borborygmus (borborygmi) Bowel sounds, especially loud gurgling sounds, resulting from hypermotility of the bowel.

boring In pain, the type of intense pain that feels like it is going through the body.

botulism A paralytic disease resulting from ingestion of a toxin in food contaminated with *Clostridium botulinum*. Botulism is associated with home-canned foods, commercially prepared products, and products not adequately heated to destroy toxins. Initial symptoms include diplopia, dysphagia, and dysarthria. Illness may be mild or severe, with paralysis, respiratory failure, and death.

Bouchard's nodes Swelling at the proximal interphalangeal joints in osteoarthritis involving the hands.

bowel training A program for patients with neurologic problems that is designed to include a combination of suppository use and a consistent toileting schedule.

boxer's ear See *cauliflower ear*.

bradycardia Slowness of the heart rate; characterized as a pulse rate less than 50 to 60 beats/min.

bradydysrhythmia An abnormal heart rhythm characterized by a heart rate less than 60 beats/min.

bradykinesia Slow or no movement, as seen in a patient with Parkinson disease; also called "akinesia."

brain abscess A collection of pus that forms in the extradural, subdural, or intracerebral area of the brain as a result of a purulent infection, usually due to bacteria invading the brain directly or indirectly.

brain attack Stroke; disruption in the normal blood supply to the brain, either as an interruption in blood flow (ischemic stroke) or as bleeding within or around the brain (hemorrhagic stroke). A medical emergency that occurs suddenly, a stroke should be treated immediately to prevent neurologic deficit and permanent disability. Formerly called "cerebrovascular accident," the National Stroke Association now uses the term "brain attack" to describe stroke.

brain herniation syndrome In the patient with untreated increased intracranial pressure, protrusion (herniation) of the brain downward toward the brainstem or laterally from a unilateral lesion within one cerebral hemisphere, causing irreversible brain damage and possibly death.

breast One of a pair of mammary glands that develop in response to secretions from the hypothalamus, pituitary gland, and ovaries. Breasts are an accessory of the reproductive system meant to nourish the infant after birth. They also are organs for sexual arousal in the mature adult.

breast augmentation Cosmetic surgical procedure to enhance the size, shape, or symmetry of the breasts.

breast-conserving surgery Surgical method for breast cancer that removes the bulk of the tumor rather than the entire breast.

Broca's aphasia See *expressive aphasia*.

Broca's area An important speech area of the cerebrum. It is located in the frontal lobe and is composed of neurons responsible for the formation of words, or speech.

bronchoscopy Insertion of a tube in the airway, usually as far as the secondary bronchi, for the purpose of visualizing airway structures and obtaining tissue samples for biopsy or culture.

Brown-Séquard syndrome A condition caused by cervical injuries; generally results from penetrating injuries that cause hemisection of the spinal cord or injuries that affect half of the spinal cord. Motor function, proprioception, vibration, and deep touch sensations are lost on the same side of the body as the lesion (ipsilateral). On the opposite side of the body (contralateral), the sensations of pain, temperature, and light touch are affected.

bruit Swishing sound in the larger arteries (carotid, aortic, femoral, and popliteal) that can be heard with a stethoscope or Doppler probe; may indicate narrowing of the artery and is usually associated with atherosclerotic disease.

bulbar Pertaining to the muscles involved in facial expression, chewing, and speech.

bulimia nervosa An eating disorder that is characterized by episodes of binge eating in which the patient ingests a large amount of food in a short time, followed by purging behavior such as self-induced vomiting or excessive use of laxatives and diuretics.

bunion Hallux valgus deformity of the foot in which lateral deviation of the great toe causes the first metatarsal head to become enlarged.

bunionectomy Surgical removal of the hallux valgus deformity (bunion) of the foot.

bursae The small sacs lined with synovial membrane that are located at joints and bony prominences to prevent friction between bone and structures adjacent to bone.

butterfly rash A dry, scaly, raised rash on the face; the major skin manifestation of systemic lupus erythematosus.

C

C fiber Unmyelinated or poorly myelinated fiber found in muscle, periosteum, and viscera; conducts thermal, chemical, and strong mechanical impulses that produce diffuse, persistent, and dull, burning, or aching sensations.

cachexia Extreme body wasting and malnutrition that develop from an imbalance between food intake and energy use.

calculi An abnormal formation of a mass of mineral salts that can occur in the body; forms in the kidney when excess calcium precipitates out of solution; also called "stones."

calculous cholecystitis Inflammation of the gallbladder usually following and created by obstruction of the cystic duct by a stone (calculus).

callus The loose, fibrous, vascular tissue that forms at the site of a fracture as the first phase of healing and is normally replaced by hard bone as healing continues.

calyx The anatomic term for a cuplike structure.

Canadian Triage Acuity Scale (CTAS) A standardized model for triage in which lists of

descriptors are used to establish the triage level.

cancellous The softer tissue inside bones that contains large spaces, or trabeculae, that are filled with red and yellow marrow.

cancer control See *cytoreductive surgery*.

candidiasis An infection caused by the fungus *Candida albicans*.

canthus The place where the upper and lower eyelids meet at the corner of either side of the eye.

capillary closing pressure The amount of pressure needed to occlude skin capillary blood flow.

capillary leak syndrome The response of capillaries to the presence of biologic chemicals (mediators) that change blood vessel integrity and allow fluid to shift from the blood in the vascular space into the interstitial tissues.

Caplan's syndrome The presence of pneumoconiosis and rheumatoid nodules in the lungs; noted primarily in coal miners and asbestos workers.

capsule The layer of fibrous tissue on the outer surface of the kidney, which provides protection and support. The renal capsule itself is surrounded by layers of fat and connective tissue.

carboxyhemoglobin Carbon monoxide on oxygen-binding sites of the hemoglobin molecule.

carcinoembryonic antigen (CEA) An oncofetal antigen that may be elevated in 70% of people with colorectal cancer. CEA is not specifically associated with the colorectal cancer and may be elevated in the presence of other benign or malignant diseases and in smokers. CEA is often used to monitor the effectiveness of treatment and to identify disease recurrence.

carcinogen Any substance that changes the activity of the genes in a cell so that the cell becomes a cancer cell.

carcinogenesis Cancer development.

cardiac axis In electrocardiography (ECG), the direction of electrical current flow in the heart. The relationship between the cardiac axis and the lead axis is responsible for the deflections seen on the ECG pattern.

cardiac catheterization The most definitive but most invasive test in the diagnosis of heart disease; involves passing a small catheter into the heart and injecting contrast medium.

cardiac index A calculation of cardiac output requirements to account for differences in body size; determined by dividing the cardiac output by the body surface area.

cardiac output (CO) The volume of blood ejected by the heart each minute; normal range in adults is 4 to 7 L/min.

cardiac rehabilitation The process of actively assisting the patient with cardiac disease to achieve and maintain a productive life while remaining within the limits of the heart's ability to respond to increases in activity and stress. *Phase 1* begins with the acute illness and ends with discharge from the hospital. *Phase 2*

begins after discharge and continues through convalescence at home. *Phase 3* refers to long-term conditioning.

cardiac resynchronization therapy (CRT) In patients with some types of heart failure, the use of a permanent pacemaker alone or in combination with an implantable cardioverter-defibrillator to provide biventricular pacing.

cardiac tamponade Compression of the myocardium by fluid that has accumulated around the heart; this compresses the atria and ventricles, prevents them from filling adequately, and reduces cardiac output.

cardiogenic shock Post-myocardial infarction heart failure in which necrosis of more than 40% of the left ventricle has occurred; also called "class IV heart failure."

cardiomegaly Enlarged heart.

cardiomyopathy A subacute or chronic disease of cardiac muscle; classified into four categories based on abnormalities in structure and function: dilated, hypertrophic, restrictive, and arrhythmogenic.

cardiopulmonary bypass (CPB) Diversion of the blood from the heart to a bypass machine, where it is heparinized, oxygenated, and returned to the circulation through a cannula placed in the ascending aortic arch or femoral artery to provide oxygenation, circulation, and hypothermia during induced cardiac arrest for coronary artery bypass surgery. This process ensures a motionless operative field and prevents myocardial ischemia.

cardiopulmonary resuscitation (CPR) A procedure that involves ventilating the patient who has stopped breathing, as well as giving chest compressions in the absence of a carotid pulse.

cardioversion A synchronized countershock that may be performed in emergencies for hemodynamically unstable ventricular or supraventricular tachydysrhythmias or electively for stable tachydysrhythmias that are resistant to medical therapies. The shock depolarizes a critical mass of myocardium simultaneously during intrinsic depolarization and is intended to stop the re-entry circuit and allow the sinus node to regain control of the heart.

carina The point at which the trachea branches into the right and left mainstem bronchi.

caring A process, set of actions, and attitude that show genuine physical and emotional concern for others.

carotid endarterectomy Removal of atherosclerotic plaque from the inner lining of the carotid artery to open the artery enough to re-establish blood flow and decrease risk for brain attack. This surgical procedure prevents progression of brain attack in symptomatic patients with recurrent transient ischemic attacks or carotid stenosis.

carotid sinus massage A method of vagal stimulation of the cardiac conduction system in which the physician massages over one carotid artery for a few seconds and observes for a change in cardiac rhythm. Massaging the

carotid sinus causes vagal stimulation, thus slowing sinoatrial and atrioventricular nodal conduction.

carpal tunnel syndrome (CTS) A common condition in which the median nerve in the wrist becomes compressed, causing pain and numbness.

carrier (1) A person who harbors an infectious agent without symptoms of active disease; (2) in genetics, a person who has one mutated allele for a recessive genetic disorder. A carrier does not usually have any manifestations of the disorder but can pass the mutated allele to his or her children.

case management The process of assessment, planning, implementation, evaluation, and interaction for patients who have complex health problems and incur a high cost to the health care system. Goals include promoting quality of life, decreasing fragmentation and duplication of care across health care settings, and maintaining cost-effectiveness.

caseation necrosis A type of necrosis in which tissue is turned into a granular mass.

cast A rigid device that immobilizes the affected body part while allowing other body parts to move. It is most commonly used for fractures but may also be applied to correct deformities (e.g., clubfoot) or to prevent deformities (e.g., those seen in some patients with rheumatoid arthritis).

catabolism Any destructive metabolic process by which organisms convert substances into excreted compounds.

cataract A lens opacity that distorts the image projected onto the retina.

catechol O-methyltransferase (COMT) inhibitors Enzymes that inactivate dopamine, thereby blocking dopamine activity and increasing the effectiveness of levodopa; a class of drugs prescribed for patients with Parkinson disease.

catecholamines Hormones (dopamine, epinephrine, and norepinephrine) released by the adrenal medulla in response to stimulation of the sympathetic nervous system.

cation Ion that has a positive charge.

cauliflower ear A deformed and hardened auricle caused by trauma and resulting in a hematoma that hardens unless the blood is removed by needle aspiration; also called "boxer's ear."

cell-mediated immunity Microbial resistance that is mediated by the action of specifically sensitized T-lymphocytes.

cellulitis An acute, spreading, edematous inflammation of the deep subcutaneous tissues; usually caused by infection of a wound or burn.

central cord syndrome A condition caused by cervical injuries that involve lesions of the central portion of the spinal cord. Loss of motor function is more pronounced in the upper extremities than in the lower extremities; varying degrees and patterns of sensation remain intact.

central IV therapy IV therapy in which a vascular access device (VAD) is placed in a

central blood vessel, such as the superior vena cava.

cerebral angiography (arteriography) Visualization of the cerebral circulation (carotid and vertebral arteries) after injecting a contrast medium into an artery (usually the femoral).

cerebral blood flow (CBF) Useful in evaluating cerebral vasospasm; can be measured in many areas of the brain with the use of radioactive substances.

cerebral perfusion pressure (CPP) The pressure gradient over which the brain is perfused. It is influenced by oxygenation, cerebral blood volume, blood pressure, cerebral edema, and intracranial pressure (ICP) and is determined by subtracting the mean ICP from the mean arterial pressure. A cerebral perfusion pressure above 70 mm Hg is generally accepted as an appropriate goal of therapy.

cerebral salt-wasting (CSW) The primary cause of hyponatremia in the neurosurgical population; characterized by hyponatremia, decreased serum osmolality, and decreased blood volume. It is thought to result from the extrarenal influence of atrial natriuretic factor.

cerumen The wax produced by glands within the external ear canal; helps protect and lubricate the ear canal.

cervical polyp Tumor that arises from the mucosa and extends to the opening of the cervical os. Polyps result from hyperplasia of the endocervical epithelium, inflammation, or an abnormal local response to hormonal stimulation or localized vascular congestion of the cervical blood vessels. Polyps are the most common benign growth of the cervix.

cervix The lower, narrowed portion of the uterus that extends into the vagina. It is the passage site for sperm to enter the uterus and the passage site for menstrual flow to exit the uterus.

chalazion An inflammation of a sebaceous gland in the eyelid.

chancre The ulcer that is the first sign of syphilis. It develops at the site of entry (inoculation) of the organism, usually 3 weeks after exposure. The lesion may be found on any area of the skin or mucous membranes but occurs most often on the genitalia, lips, nipples, and hands and in the oral cavity, anus, and rectum.

chancroid A sexually transmitted disease characterized by painful genital ulcerations and caused by infection with *Haemophilus ducreyi*. Infection develops as a result of sexual exposure or self-contamination from a lesion elsewhere on the body. Incubation period varies from 3 to 10 days. A tender papule appears at the site of inoculation and rapidly breaks down to form an irregularly shaped, deep ulcer that has a purulent discharge and bleeds easily.

chelation A general term referring to a drug or substance that binds or attaches to another substance.

chemoreceptor Specialized sensory receptor in the bifurcation of the carotid arteries and in the aortic arch; sensitive to hypoxemia.

When stimulated, the carotid chemoreceptors send impulses along Hering's nerves and the aortic chemoreceptors send impulses along the vagus nerves to activate a vasoconstrictor response.

chemotaxin Substance secreted by damaged tissues and blood vessels that attracts neutrophils and macrophages so that phagocytosis can occur; also called "leukotaxin."

chemotherapy The treatment of cancer with chemical agents that have systemic effects; used to cure and to increase survival time.

chemotherapy-induced peripheral neuropathy (CIPN) The loss of sensory or motor function of peripheral nerves associated with exposure to certain anticancer drugs.

chest tube A drain placed in the pleural space to allow closed-chest drainage, which restores intrapleural pressure and allows re-expansion of the lung after surgery in patients who have undergone thoracotomy (incision of the chest wall).

Cheyne-Stokes respirations Common sign of nearing death in which apnea alternates with periods of rapid breathing.

choked disc See *papilledema*.

cholecystectomy The surgical removal of the gallbladder.

cholecystitis Inflammation of the gallbladder.

cholecystokinin A hormone that stimulates digestive juices and may work with leptin to increase or decrease appetite.

choledochojejunostomy Surgical anastomosis of the common bile duct with the jejunum.

cholelithiasis The presence of gallstones.

cholesteatoma A benign overgrowth of squamous cell epithelium.

cholinergic crisis Overmedication with cholinesterase inhibitors.

cholinesterase inhibitors Drugs that improve cholinergic neurotransmission in the central nervous system by delaying the destruction of acetylcholine by acetylcholinesterase, thus delaying the onset of cognitive decline. These are approved for symptomatic treatment of Alzheimer's disease but do not affect the course of the disease.

chondrogenic Originating from cartilage.

chondroitin A supplement that may play a role in strengthening cartilage.

choreiform movement Rapid, jerky movement.

chorioretinitis Inflammation of both the choroid and the retina.

chronic Having a slow onset and symptoms that persist for an extended period.

chronic calcifying pancreatitis (CCP) Alcohol-induced chronic pancreatitis that is characterized by protein precipitates that plug the ducts and lead to ductal obstruction, atrophy, and dilation. The epithelium of the ducts undergoes histologic changes, resulting in metaplasia (cell replacement) and ulceration. This inflammatory process causes fibrosis of the pancreatic tissue.

chronic cancer pain Persistent or recurrent pain that results from cancer or another progressive disease or life-threatening condition.

chronic constrictive pericarditis A fibrous thickening of the pericardium that prevents adequate filling of the ventricles and eventually results in cardiac failure; caused by chronic pericardial inflammation due to tuberculosis, radiation therapy, trauma, kidney failure, or metastatic cancer.

chronic fatigue syndrome (CFS) A chronic illness characterized by severe fatigue for 6 months or longer, usually following flu-like symptoms. At least four of the following criteria are required for diagnosis: sore throat; substantial impairment in short-term memory or concentration; tender lymph nodes; muscle pain; multiple joint pain with redness or swelling; headaches of a new type, pattern, or severity; unrefreshing sleep; and postexertional malaise lasting more than 24 hours.

chronic gastritis A patchy, diffuse inflammation of the mucosal lining of the stomach. Chronic gastritis usually heals without scarring but can progress to hemorrhage and ulcer formation.

chronic health problem A condition that has existed for at least 3 months.

chronic hepatitis Chronic liver inflammation that usually occurs as a result of hepatitis B or C. Superimposed infection with hepatitis D (HDV) in patients with chronic HBV may also result in chronic hepatitis. Can lead to cirrhosis and liver cancer.

chronic non-cancer pain Persistent or recurrent pain associated with a tissue injury that has healed or is not associated with cancer, such as arthritis.

chronic obstructive pancreatitis Pancreatitis that develops from inflammation, spasm, and obstruction of the sphincter of Oddi. Inflammatory and sclerotic lesions occur in the head of the pancreas and around the ducts, causing obstruction and backflow of pancreatic secretions.

chronic obstructive pulmonary disease (COPD) Any lung disease characterized by bronchospasm and dyspnea, such as emphysema and chronic bronchitis.

chronic osteomyelitis Bone infection that persists over a long time due to misdiagnosis or inadequate treatment; also called "sub-chronic osteomyelitis."

chronic pain Pain that persists or recurs for indefinite periods (usually more than 3 months), often involves deep body structures, is poorly localized, and is difficult to describe. Also called "persistent pain."

chronic pancreatitis A progressive, destructive disease of the pancreas characterized by remissions and exacerbations. Inflammation and fibrosis of the tissue contribute to pancreatic insufficiency and diminished function of the organ.

chronic paronychia Inflammation of the skin around the nail that persists for months. People at risk for chronic paronychia are those with frequent exposure to water, such as homemakers, bartenders, and laundry workers.

chronic pyelonephritis A kidney disorder that results from repeated or continued upper

urinary tract infections or the effects of such infections.

chronic stable angina (CSA) Type of angina characterized by chest discomfort that occurs with moderate to prolonged exertion and in a pattern that is familiar to the patient.

chyme The liquid formed when food is transformed during the digestion process in the gastrointestinal tract.

cilia Hairlike projections from epithelial cells; also, the eyelids or eyelashes.

circle of Willis At the base of the brain, the ring formed by the anterior, middle, and posterior cerebral arteries where they are joined together by small communicating arteries.

circumcision The surgical removal of the prepuce or foreskin of the penis.

circumferential Referring to something that completely surrounds an extremity or the thorax.

cirrhosis Liver disease that is characterized by extensive scarring of the liver and is usually caused by a chronic irreversible reaction to hepatic inflammation and necrosis; disease typically develops insidiously and has a prolonged, destructive course.

classic heat stroke A form of heat stroke in which the body's ability to dissipate heat is significantly impaired; occurs over time as a result of long-term exposure to a hot, humid environment such as a home without air-conditioning in the high heat of the summer.

claudication Pain in the muscles resulting from an inadequate blood supply.

climacteric The phase of a woman's life from the initial decline in the amount of estrogen produced by the ovaries to the end of symptoms. The lay term for this phase is "the change of life."

clinical practice guideline An "official recommendation" based on evidence to diagnose and/or manage a health problem (e.g., pain management).

clinically competent The condition of being legally competent and having decisional capacity.

clitoris A small, cylindric organ of the external female genitalia that is composed of erectile tissue with a high concentration of sensory nerve endings.

clonic Pertaining to a state of alternating muscle stiffness followed by rhythmic jerking motions, as in a tonic-clonic seizure.

clonic seizure A type of generalized seizure lasting several minutes and characterized by muscle contraction and relaxation.

clonus The sudden, brief, jerking contraction of a muscle or muscle group often seen in seizures.

closed fracture A fracture that does not extend through the skin and therefore has no visible wound; also called "simple fracture."

closed head injury A type of traumatic primary brain injury that occurs as the result of blunt trauma; the integrity of the skull is not violated, and damage to brain tissue depends on the degree and mechanisms of injury.

closed reduction A nonsurgical method for managing a simple fracture. While applying a manual pull, or traction, on the bone, the health care provider manipulates the bone ends so they realign.

clubbing Changes in the tissue beds of the fingers and toes, with the base of the nail becoming spongy; results from chronic oxygen deprivation in the tissue beds.

cluster headache A type of oculotemporal or oculofrontal headache marked by unilateral, excruciating, nonthrobbing pain that is felt deep in and around the eye and may radiate to the forehead, temple, cheek, ear, occiput, or neck. Average duration is 10 to 45 minutes. Headaches occur every 8 to 12 hours and up to 24 hours daily at the same time for about 6 to 8 weeks (hence the term "cluster"), followed by remission for 9 months to a year. Cause and mechanism are unknown but have been attributed to vasoreactivity and oxyhemoglobin desaturation.

CO₂ narcosis Loss of sensitivity to high levels of PaCO₂. For these patients, the stimulus to breathe is a decreased arterial oxygen level.

coagulopathy Clotting abnormalities.

cochlea The spiral organ of hearing within the inner ear.

cognition The ability of the brain to process, store, retrieve, and manipulate information.

cognitive therapist A member of the rehabilitative health care team, usually a neuropsychologist, who works primarily with patients who have experienced head injuries and have cognitive impairments.

cohorting The practice of grouping patients who are colonized or infected with the same pathogen.

coitus Sexual intercourse.

cold antibody anemia A form of immunohemolytic anemia (in which the immune system attacks a person's own red blood cells for unknown reasons) that occurs with complement protein fixation on immunoglobulin M (IgM). In this condition, the arteries in the hands and feet constrict profoundly in response to cold temperatures or stress.

cold phase A phase after peripheral nerve trauma resulting in complete denervation in which the skin appears cyanotic, mottled, or reddish blue and feels cool compared with the contralateral, unaffected extremity. The cold phase follows the warm phase, which lasts 2 to 3 weeks after injury.

colectomy Surgical removal of part or all of the colon.

collaboration The planning, implementing, and evaluation of patient care using an interdisciplinary (ID) plan of care.

collaborative nursing function Activity that is mutually determined by the nurse and the physician or other health care team member or that is directed or prescribed by the health care provider but requires nursing judgment to perform.

collateral circulation Circulation that provides blood to an area with altered

tissue perfusion through smaller vessels that develop and compensate for the occluded vessels.

colon interposition A surgical procedure that may be performed in patients with an esophageal tumor when the tumor involves the stomach or the stomach is otherwise unsuitable for anastomosis. In colon interposition, a section of right or left colon is removed and brought up into the thorax to substitute for the esophagus.

colon resection Surgery performed for colorectal cancer in which the tumor and regional lymph nodes are removed.

colonization The presence of microorganisms in the tissues of the host without causing symptomatic disease.

colonoscopy The endoscopic examination of the entire large bowel.

colostomy The surgical creation of an opening between the colon and the surface of the abdomen.

colposcopy Examination of the cervix and vagina using a colposcope, which allows three-dimensional magnification and intense illumination of epithelium with suspected disease. This procedure can locate the exact site of precancerous and malignant lesions for biopsy.

comatose A state of being unconscious and unarousable.

comedones Plural form of “comedo.” Blackheads and whiteheads, the noninflammatory lesions of acne.

command center See *emergency operations center*.

commando (co-mandible) procedure (COMBined neck dissection, MANDibulectomy, and Oropharyngeal resection)

A procedure in which the surgeon removes a segment of the mandible with the oral lesion and performs a radical neck dissection.

comminuted fracture A type of fracture that involves fragmentation of the bone.

commitment Occurrence in which early embryonic cells start changing into differentiated cells.

communicable The ability of an infection, such as influenza, to be transmitted from person to person.

comorbidity Pre-existing disease state that must be included in patient assessment in regard to how the condition might adversely affect a seemingly unrelated health problem.

compartment syndrome A condition in which increased tissue pressure in a confined anatomic space causes decreased blood flow to the area, leading to hypoxia and pain.

compensated cirrhosis A form of cirrhosis in which the liver has significant scarring but is still able to perform essential functions without causing significant symptoms.

compensatory mechanism The means of producing compensation; also called “adaptive mechanism.”

complement activation and fixation Actions triggered by some classes of antibodies that can remove or destroy antigen.

complementary and alternative medicine

The broad range of healing philosophies, approaches, and therapies that mainstream Western medicine does not commonly use.

complete spinal cord injury An injury in which the spinal cord has been severed or damaged in a way that eliminates all innervation below the level of the injury.

complex partial seizure A type of partial seizure that occurs in patients with epilepsy, causing loss of consciousness for 1 to 3 minutes. Characteristic behaviors known as “automatisms” may occur, such as lip smacking or picking at clothes. The patient may experience amnesia after the seizure. Because the area of the brain most often involved is the temporal lobe, complex partial seizures are often called “psychomotor seizures” or “temporal lobe seizures.”

complex regional pain syndrome (CRPS) A complex disorder that includes debilitating pain, atrophy, autonomic dysfunction (excessive sweating, vascular changes), and motor impairment (most notably muscle paresis), probably caused by an abnormally hyperactive sympathetic nervous system. This syndrome most often results from traumatic injury and commonly occurs in the feet and hands; formerly called “reflex sympathetic dystrophy (RSD).”

compliance In respiratory physiology, a measure of elasticity within the lung. Also, a patient’s fulfillment of a caregiver’s prescribed course of treatment.

compound fracture See *open fracture*.

compression fracture A fracture that is produced by a loading force applied to the long axis of cancellous bone. These fractures commonly occur in the vertebrae of patients with osteoporosis.

computed tomography coronary angiography (CTCA) 64-slice diagnostic scan used to diagnose coronary artery disease in symptomatic patients.

computed tomography (CT) scanning Use of a computer to take pictures at many horizontal levels, or slices, of the area being studied. The cross-sectional slices build up three-dimensional pictures; a contrast medium may be used to enhance the image.

concentration gradient Movement across a membrane from an area of higher concentration to an area of lower concentration.

concussion A type of closed head injury that is caused by blunt trauma (e.g., a blow to the head) and is characterized by a brief loss of consciousness.

conductive hearing loss Hearing loss that results from any physical obstruction of sound wave transmission (e.g., a foreign body in the external canal, a retracted or bulging tympanic membrane, or fused bony ossicles).

conductivity The ability of a cell to transmit an electrical stimulus from cell membrane to cell membrane.

congestive heart failure (CHF) Former term for “left-sided heart failure.” Categorized as either systolic heart failure or diastolic heart

failure that may be acute or chronic and mild to severe.

conization The removal of a cone-shaped sample of tissue from the cervix for cytologic study.

conjunctivae The mucous membranes of the eye that line the undersurface of the eyelids (palpebral conjunctiva) and cover the sclera (bulbar conjunctiva).

connective tissue disease (CTD) A group of diseases that are the major focus of rheumatology (the study of rheumatic diseases); most are musculoskeletal disorders.

consensual response In assessing pupillary reaction to light, a slight constriction of the pupil of the eye not being tested when a penlight is brought in from the side of the patient’s head and shined into the eye being tested as soon as the patient opens his or her eyes.

consolidation Solidification; lack of air spaces in the lung, such as occurs in pneumonia.

contact laser prostatectomy (CLP) Procedure for treating benign prostatic hyperplasia that uses laser energy to coagulate excess tissue. Also called “interstitial laser coagulation (ILC).”

Contact Precautions Infection control guidelines from the Centers for Disease Control and Prevention; used for patients with infections spread by direct contact or contact with items in the patient’s environment, such as pediculosis.

contiguous Something in direct contact with, or adjacent to, another area or structure.

continence The ability to voluntarily control emptying the bladder and colon. Continence is a learned behavior whereby a person can suppress the urge to urinate until a socially appropriate location is available.

continuous feeding A method of tube feeding in which small amounts of enteral product are continuously infused (by gravity drip or by a pump or controller device) over a specified time.

continuous positive airway pressure (CPAP) A respiratory treatment that improves obstructive sleep apnea in patients with heart failure.

contractility The ability of a cell to contract in response to an impulse. In cardiac electrophysiology, the ability of atrial and ventricular muscle cells to shorten their fiber length in response to electrical stimulation, generating sufficient pressure to propel blood forward. Contractility is the mechanical activity of the heart.

contraction The closure of a wound as new collagen replaces damaged tissue, pulling the wound edges inward along the path of least resistance.

contralateral Pertaining to the opposite side.

contrecoup injury Bruising of the brain tissue, with damage occurring on the side opposite the site of impact.

controller A stationary, pole-mounted electronic device that uses a sensor to monitor fluid flow during infusion therapy and to detect flow interruption.

contusion A bruise; when referring to closed head injury, a bruising of brain tissue usually found at the site of impact (coup injury). Compare with *contrecoup injury*.

cor pulmonale Right-sided heart failure caused by pulmonary disease.

cordectomy Excision of a vocal cord in surgery for laryngeal cancer.

cordotomy Surgical technique in which the surgeon cuts the pain pathways at the midline portion of the spinal cord, before nerve impulses ascend to the spinothalamic tract. Used to relieve intractable pain in patients with metastatic cancer by interrupting the transmission of pain.

cornea The clear layer that forms the external coat on the front of the eye.

corneal abrasion Scrape or scratch of the cornea that disrupts its integrity.

corneal ulceration Deep disruption of the corneal epithelium that extends into the stromal layer and is caused by bacteria, protozoa, or fungi.

coronary artery bypass graft A surgical procedure in which occluded coronary arteries are bypassed with the patient's own venous or arterial blood vessels or synthetic grafts.

coronary artery calcium (CAC) score A measure of the amount of coronary artery calcification present.

coronary artery disease (CAD) Disease affecting the arteries that provide blood, oxygen, and nutrients to the myocardium; partial or complete blockage of the blood flow through the coronary arteries, causing ischemia and infarction of the myocardium, angina pectoris, and acute coronary syndromes.

coronary artery vasculopathy (CAV) A form of coronary artery disease that presents as diffuse plaque in the arteries of the donor heart in patients who have received a heart transplant.

cortex The outer layer of an organ or body structure.

cortical A term referring to compact bone of the shaft of a bone.

corticosteroids The hormones produced and secreted by the adrenal cortex; also called "adrenal steroids."

cortisol The main glucocorticoid produced by the adrenal cortex.

coryza The common cold, or acute viral rhinitis.

cough assist A technique for assisting the tetraplegic patient to cough. Place his or her hands on either side of the rib cage or upper abdomen below the diaphragm; then, as the patient exhales, push upward to help expand the lungs and cough.

craniotomy Surgical incision into the cranium.

creatine kinase (CK) An enzyme specific to cells of the brain, myocardium, and skeletal muscle. Its appearance in the blood indicates tissue necrosis or injury, with levels following a predictable rise and fall during a specified period.

Crédé maneuver A technique used to assist in urination in which a patient places his or her hand in a cupped position directly over the bladder area and pushes inward and downward gently as if massaging the bladder to empty.

cremasteric reflex Stimulation of the skin on the front and inner side of the thigh retracts the testicle and scrotum on the same side. An intact reflex indicates integrity of the first lumbar nerve segment of the spinal cord.

crepitus (crepitation) A continuous grating sensation caused when irregular cartilage or bone fragments rub together and which may be felt or heard as a joint is put through passive range of motion; also, a crackling sensation that can be felt on a patient's chest, indicating that air is trapped within the tissues.

CREST syndrome In patients with systemic sclerosis, the combination of *cal*cinosis (calcium deposits), *R*aynaud's phenomenon, *e*sophageal dysmotility, *s*clerodactyly (scleroderma of the digits), and *t*elangiectasia (spider-like hemangiomas).

cricothyroidotomy Surgical procedure in which an opening is made between the thyroid cartilage and cricoid cartilage ring and results in a tracheostomy; also called "cricothyrotomy." The procedure is used in an emergency for access to the lower airways.

crises In the patient with sickle cell disease, periodic episodes of extensive cellular sickling that have a sudden onset and can occur as often as weekly or as seldom as once a year.

critical access hospital A small rural facility of 15 or fewer inpatient beds that provides around-the-clock emergency care services 7 days per week. Considered a necessary provider of health care to community residents who are not close to other hospitals in a given region.

critical thinking Purposeful, outcome-directed thinking that is used to make clinical judgments based on scientific evidence rather than on tradition or conjecture (guesswork).

cross-contamination A type of contamination in which organisms from another person or from the environment are transmitted to the patient.

cryoanalgesia The use of cold to achieve permanent ablation of nerve roots.

cryoprecipitate A highly concentrated blood product that is derived from plasma and includes clotting factors VIII and XIII, von Willebrand's factor, and fibrinogen.

cryosurgery Destruction of tissue by applying extreme cold; may reduce pain and tumor size in patients with metastatic cancer.

cryotherapy (1) A way of decreasing muscle pain by "cooling down" the area with a local, short-acting gel or cream, such as after physical therapy; (2) in ophthalmologic surgery, use of a freezing probe to repair retinal detachment.

cryptorchidism Failure of the testes to descend into the scrotum.

Cullen's sign The presence of a bluish discoloration around the umbilicus, which is an indication of intra-abdominal bleeding.

cultural competence The ability of health care provider or organization to understand and respond effectively to the cultural and linguistic needs that patients bring to the health care setting.

cultural diversity The differences among people, which may or may not be visible.

cultural sensitivity The way that one responds to cultural differences.

culture (1) A procedure for identifying a microorganism by cultivating and isolating it in tissue cultures or artificial media; (2) an integrated pattern of human behavior that is learned and transmitted to succeeding generations and includes thought, speech, action, and artifacts.

curandero A folk healer in the Mexican-American medicine system who considers health and health care from a holistic, spiritual perspective rather than the traditional scientific viewpoint.

curative surgery Surgery done to remove all cancer tissue.

Curling's ulcer Acute ulcerative gastroduodenal disease, which may develop within 24 hours of a severe burn injury because of reduced gastrointestinal blood flow and mucosal damage.

Cushing's disease (Cushing's syndrome) Hypercortisolism caused by oversecretion of hormones by the adrenal cortex.

Cushing's triad A classic yet late sign of increased intracranial pressure (ICP) manifested by severe hypertension with a widened pulse pressure and bradycardia. As ICP increases, the pulse becomes thready, irregular, and rapid. Cerebral blood flow increases in response to hypertension.

Cushing's ulcer Acute ulcerative gastroduodenal disease that may develop as a result of increased intracranial pressure.

cutaneous reflexes Superficial reflexes. Usually the plantar and abdominal reflexes are tested.

cuticle A layer of keratin at the nail fold, which attaches the nail plate to the soft tissue of the nail fold.

cyanosis Bluish or darkened discoloration of the skin and mucous membranes; results from an increased amount of deoxygenated hemoglobin.

cyclic feeding A method of tube feeding similar to continuous feeding (see definition of *continuous feeding*) except the infusion is stopped for a specified time in each 24-hour period ("down time"); the down time typically occurs in the morning to allow bathing, treatments, and other activities.

cyst Firm, flesh-colored nodule that contains liquid or semisolid material.

cystectomy (1) Removal of a cyst; (2) surgical removal of the bladder and surrounding tissue.

cystitis Inflammation of the bladder.

cystocele Herniation of the bladder into the vagina.

cytokines Small protein hormones produced by white blood cells.

cytopenia Low blood count.

cytoprotectant Drug that protects specific healthy cells; given to patients to decrease the impact of chemotherapy on normal tissues.

cytoreductive surgery Surgery done to remove part of a tumor while leaving a known amount of gross tumor behind; also called “cancer control.”

cytotoxic Having cell-damaging effects.

D

dandruff An accumulation of patchy or diffuse white or gray scales on the surface of the scalp.

dawn phenomenon In the patient with diabetes, a condition of fasting hyperglycemia resulting from a nighttime release of growth hormone that causes blood glucose elevations at about 5 to 6 AM. Providing more insulin for the overnight period helps avoid this condition.

death When illness or trauma overwhelms the compensatory mechanisms of the body and the lungs and heart cease to function.

death rattle Loud, wet respirations caused by secretions in the respiratory tract and oral cavity of a patient who is near death.

débridement The removal of infected tissue from a healing wound.

debriefing After a mass casualty incident or disaster, (1) the provision of sessions for small groups of staff in which teams are brought in to discuss effective coping strategies (critical incident stress debriefing), and (2) the administrative review of staff and system performance during the event to determine opportunities for improvement in the emergency management plan.

debris Dead cells and tissues in a wound.

decerebrate posturing Abnormal posturing and rigidity characterized by extension of the arms and legs, pronation of the arms, plantar flexion, and opisthotonos; usually associated with dysfunction in the brainstem area. Also called “decerebration.”

decerebration See *decerebrate posturing*.

decompensated cirrhosis A form of cirrhosis in which liver function is significantly impaired with obvious manifestations of liver failure.

decompressive laminectomy Removal of one or more laminae in the patient with spinal cord injury and compression; allows for cord expansion from edema if more conventional measures fail to prevent neurologic deterioration.

decorticate posturing Abnormal posturing seen in the patient with lesions that interrupt the corticospinal pathways. The arms, wrists, and fingers are flexed with internal rotation and plantar flexion of the legs. Also called “decortication.”

decortication See *decorticate posturing*.

deep tendon reflexes Tested as part of the neurologic assessment. An intact reflex arc is indicated when the muscle contracts in response to the tendon being struck with a hammer.

deep vein thrombophlebitis Presence of a thrombus associated with inflammation in the deep veins, usually in the legs. Compared with superficial thrombophlebitis, it presents a greater risk for pulmonary embolism; also called “deep vein thrombosis.”

deep vein thrombosis (DVT) Common term for deep vein thrombophlebitis.

defibrillation An asynchronous countershock that depolarizes a critical mass of myocardium simultaneously to stop the re-entry circuit, allowing the sinus node to regain control of the heart.

degradation The process of breaking down.

dehiscence A partial or complete separation of the outer layers of a wound, sometimes described as a “splitting open” of the wound.

dehydration Fluid intake less than what is needed to meet the body’s fluid needs.

delayed union Term describing a fracture that has not healed within 6 months of injury.

delegation The process of transferring to a competent person the authority to perform a selected nursing task or activity in a selected patient care situation.

delirium An acute state of confusion, usually short-term and reversible within 3 weeks. Often seen among older adults in a hospital or other unfamiliar setting.

delirium tremens (DTs) Tremors of the entire body; a symptom of alcohol withdrawal.

demand dose An amount of drug specified by the health care provider that is programmed into a patient-controlled analgesia infusion pump.

dementia A syndrome of slowly progressive cognitive decline with global impairment of intellectual function. The most common type is Alzheimer’s disease.

demyelination Destruction of myelin between the nodes of Ranvier; a major pathologic finding in Guillain-Barré syndrome.

demyelination Occurrence of multiple sclerosis in which the myelin sheath is damaged and its thickness is reduced.

deoxyribonucleic acid (DNA) The basic genetic material required for cell division and growth.

dependence A condition that causes a habitual, compulsive, and uncontrollable urge to use a substance; without the substance, the body experiences severe physiologic, psychological, and emotional disturbances.

depolarization The ability of a cell to respond to a stimulus by initiating an impulse; also called “excitability.”

depressant A drug that reduces the activity of the central nervous system, such as a benzodiazepine or barbiturate.

depressed fracture A type of skull fracture in which the bone is pressed inward into the brain tissue.

depression A response to multiple life stresses, a single situation, a primary disorder, or a problem associated with dementia; this response can range from mild, transient feelings of sadness to a severe sense of helplessness and hopelessness.

dermal appendages Collectively, the sweat and oil glands and the hair follicles. The depth of dermal appendages varies from one body area to another.

dermal papillae Fingerlike projections of dermal tissue that anchor the epidermis to the dermis.

dermatomes Specific areas of the skin that receive sensory input from spinal nerves.

dermatomyositis Polymyositis that is accompanied by a rash.

descending tracts Groups of nerves that begin in the brain and end in the spinal cord.

desquamation The shedding or peeling of skin.

diagnostic peritoneal lavage (DPL) Test that determines the presence of internal bleeding following abdominal trauma.

diagnostic surgery Surgery done to remove all or part of a suspected lesion for examination and testing; also called “biopsy.”

dialysate The solution used in dialysis. It is composed of water, glucose, sodium chloride, potassium, magnesium, calcium, and bicarbonate; dialysate composition may be altered according to the patient’s needs for treatment of electrolyte imbalances.

dialyzer The apparatus used to perform hemodialysis. Also known as the “artificial kidney,” it has four parts: a blood compartment, a dialysate compartment, a semipermeable membrane, and an enclosed structure to support the membrane.

diaphoresis Abnormally profuse sweating.

diaphysis The shaft, or elongated cylindrical portion, between the ends of a long bone.

diastole The phase of the cardiac cycle that consists of relaxation and filling of the atria and ventricles; normally about two thirds of the cardiac cycle.

diastolic blood pressure The amount of pressure/force against the arterial walls during the relaxation phase of the heart.

diastolic heart failure Heart failure that occurs when the left ventricle is unable to relax adequately during diastole, which prevents the ventricle from filling with sufficient blood to ensure adequate cardiac output.

diathermy The use of a high-frequency current to heat body tissues.

Dietary Guidelines for Americans Recommendations made by the USDA and U.S. Department of Health and Human Services to help people maintain nutritional health; updated every 5 years.

dietitian A member of the health care team who ensures patients meet their nutritional needs. Also called “nutritionist.”

diffuse axonal injury (DAI) A type of closed head injury that is usually related to high-speed acceleration/deceleration, as with motor vehicle crashes. There is significant damage to axons in the white matter, and there are lesions in the corpus callosum, midbrain, cerebellum, and upper brainstem. Patients with severe injury may present with immediate coma, and most survivors require long-term care.

diffuse light reflex A description of a light reflex that is spotty or multiple because of a changed eardrum shape from either retraction or bulging.

diffuse scleroderma Skin thickening on the trunk, face, and proximal and distal extremities in patients with systemic sclerosis.

diffusion The spontaneous, free movement of particles (solute) across a permeable membrane down a concentration gradient; that is, from an area of higher concentration to an area of lower concentration.

digestion The mechanical and chemical process in which complex foodstuffs are broken down into simpler forms that can be used by the body.

digitalis toxicity A reaction to therapy with digitalis derivatives (digoxin) that is identified by monitoring serum digoxin and potassium levels (hypokalemia potentiates digitalis toxicity). Signs of toxicity are nonspecific (anorexia, fatigue, changes in mental status). Toxicity may cause dysrhythmia, most commonly premature ventricular contractions.

dilated cardiomyopathy (DCM) A type of cardiomyopathy that involves extensive damage to the myofibrils and interference with myocardial metabolism. There is normal ventricular wall thickness but dilation of both ventricles and impairment of systolic function.

dilation Increase in the diameter of blood vessels.

diplopia Double vision.

direct contact A mode of infection transmission in which microorganisms are transferred directly by physical contact from one person to another.

direct current stimulation (DCS) The placement of an implantable device to promote bone fusion; used as an adjunct for patients for whom spinal fusion may be difficult.

direct inguinal hernia A sac formed from the peritoneum that contains a portion of the intestine and passes through a weak point in the abdominal wall.

direct response Pupil constriction in response to bringing a penlight in from the side of the patient's head and shining the light in the eye being tested as soon as the patient opens his or her eyes.

directly observed therapy (DOT) A technique in which a health care professional watches the patient swallow prescribed drugs.

disabling health problem Any physical or mental health problem that can cause disability.

disaster A mass casualty incident in which the number of casualties exceeds the resource capabilities of a particular community or hospital facility.

disaster triage tag system A system that categorizes triage priority by colored and numbered tags.

discoid lesion Round lesion in patients who have discoid lupus erythematosus; evident when exposed to sunlight or ultraviolet light.

disease-modifying antirheumatic drugs (DMARDs) Drugs prescribed to slow the progression of mild rheumatoid disease before it worsens, such as hydroxychloroquine, sulfasalazine, or minocycline.

disequilibrium A condition in which the hydrostatic pressure is not the same in the two fluid spaces on either side of a permeable membrane.

disinfection A method of infection control in which the level of disease-causing organisms is reduced but the organisms are not killed; adequate when an item is entering a body area that has resident bacteria or normal flora, such as the respiratory tract.

diskitis Disk inflammation.

dislocation of a joint Occurrence of the articulating surfaces of two or more bones moving away from each other.

dissociate The act of separating and releasing ions.

distal protection device A device that is placed beyond (distal to) the stenosis during an angioplasty/stenting procedure for the purpose of catching debris that breaks off during the procedure.

divalent cation An ion having two positive charges.

diverticula Sacs resulting from the herniation of the mucosa and submucosa of a tubular organ into surrounding tissue.

diverticulitis The inflammation of one or more diverticula.

diverticulosis The presence of many abnormal pouchlike herniations (diverticula) in the wall of the intestine.

dizziness A disturbed sense of a person's relationship to space.

DNA replication The process of making a new copy of an entire strand of DNA.

dopamine agonist A class of drugs that mimic dopamine. Dopamine agonists stimulate dopamine receptors and are typically the most effective during the first 3 to 5 years of use. Prescribed for the patient with Parkinson disease to reduce dyskinesias (problems with movement).

dose (1) In radiation therapy, the amount of radiation absorbed by recipient tissue during radiation therapy as determined by intensity of exposure, duration of exposure, and closeness of the radiation source to the cells; (2) the amount of drug or other substance to be administered at one time.

dose-dense chemotherapy Chemotherapy that uses higher doses more often for aggressive cancer treatment, especially breast cancer.

double-barrel stoma The least common type of colostomy, which is created by dividing the bowel and bringing both the proximal and distal portions to the abdominal surface to create two stomas.

doubling time The amount of time it takes for a tumor to double in size.

Dressler's syndrome Pericarditis, fever, and pericardial and pleural effusions occurring together from 1 to 12 weeks after myocardial infarction.

droplet The small particles produced when a person coughs or sneezes; may be involved in indirect transmission of infection.

Droplet Precautions Infection control guidelines from the Centers for Disease Control and Prevention; used for patients with infections spread by the droplet transmission route, such as influenza.

drug holiday Period of time lasting up to 10 days in which the patient with Parkinson disease receives no drug therapy.

dual x-ray absorptiometry (DXA) A type of radiographic scan that measures bone mineral density in the hip, wrist, or vertebral column; used as a screening and diagnostic tool for diagnosis and for follow-up evaluation of treatment of osteoporosis.

ductal carcinoma in situ (DCIS) An early, noninvasive form of breast cancer in which cancer cells are located within the duct and have not invaded the surrounding fatty breast tissue.

ductal ectasia A benign breast disease caused by dilation and thickening of the collecting ducts in the subareolar area. The ducts become distended and filled with cellular debris, which activates an inflammatory response. It is usually seen in women approaching menopause.

dull A term that describes the medium-pitched, soft, thudlike sound over a solid organ (e.g., liver) that is obtained upon percussion of the abdomen.

dumping syndrome A constellation of vasomotor symptoms that typically occur within 30 minutes after eating; believed to occur as a result of the rapid emptying of gastric contents into the small intestine, which shifts fluid into the gut and causes abdominal distention. Early manifestations include vertigo, tachycardia, syncope, sweating, pallor, and palpitations.

Dupuytren's contracture A slowly progressive contracture of the palmar fascia that results in flexion of the fourth or fifth digit of the hand and occasionally affects the third digit. Although a fairly common problem, the cause is unknown. It usually occurs in older men, tends to occur in families, and can be bilateral.

durable power of attorney (DPOA) for health care A legal document in which a person appoints someone else to make health care decisions in the event he or she becomes incapable of making decisions.

dysarthria Slurred speech.

dysfunctional uterine bleeding (DUB) A nonspecific term to describe bleeding that is excessive or abnormal in amount or frequency without predisposing anatomic or systemic conditions. Such bleeding occurs most often at either end of the span of a woman's reproductive years, when ovulation is becoming established or when it is becoming irregular at menopause.

dyskinesia Difficulty with movement.

dysmenorrhea Painful menstruation.

dysmetria The inability to direct or limit movement.

dyspareunia Painful sexual intercourse.

dyspepsia Indigestion or heartburn following meals.

dysphagia Difficulty in swallowing.

dyspnea Difficulty in breathing or breathlessness.

dyspnea on exertion (DOE) Dyspnea that is associated with activity, such as climbing stairs.

dysrhythmia A disorder of the heartbeat involving a disturbance in cardiac rhythm; irregular heartbeat.

dystrophic Pertaining to or characterized by dystrophy; abnormal.

dystrophin A muscle protein that maintains muscle integrity by sending signals to coordinate smooth, synchronous muscle fiber contraction. Faulty action of this protein causes muscular dystrophy.

dysuria Painful urination.

E

early-onset seizure Seizure that occurs within 7 days of a head injury.

Eaton-Lambert syndrome A form of myasthenia gravis that affects the muscles of the trunk and the pelvic and shoulder girdles; often observed in combination with small cell carcinoma of the lung. Although weakness increases after exertion, there may be a temporary increase in muscle strength during the first few contractions, followed by a rapid decline.

ecchymoses Large purple, blue, or yellow bruises of the skin resulting from small hemorrhages; these bruises are larger than petechiae.

ecchymotic Pertaining to a bruise.

ECG caliper A measurement tool used in analysis of an electrocardiographic (ECG) rhythm strip.

echocardiography In cardiovascular assessment, the use of ultrasound waves to assess cardiac structure and mobility, particularly of the valves; a noninvasive, risk-free test that is easily performed at the bedside or on an ambulatory care basis.

echolalia Automatic repetition of what another person says.

ectopic Out of place.

ectopic beats Heartbeats generated outside the normal conduction system in the ventricles; a cardiac manifestation of hyperkalemia.

ectropion A turning outward and sagging of the eyelid, which is caused by relaxation of the orbicular muscle.

edema Tissue swelling as a result of the accumulation of excessive fluid in the interstitial spaces.

edentulous Without teeth.

efferent arterioles The extremely small blood vessels that carry the remaining blood out of the glomerulus (once the glomerulus has filtered the blood to make urine) and into one of two additional capillary systems (the peritubular capillaries or the vasa recta).

effluent Drainage.

effusion An accumulation of fluid, such as in a joint (where it may limit movement).

ejection fraction The percentage of blood ejected from the heart during systole.

elastin The major component of the elastic fibers that are scattered among the collagen fibers. Elasticity of the skin depends on both the amount and quality of the elastic fibers.

electrical bone stimulation The use of an electronic device (e.g., magnetic coils applied on the skin or over a cast to deliver a pulsed magnetic field) to promote bone union after a fracture. The exact mechanism of action is unknown, but this procedure is based on research showing that bone has inherent electrical properties that are used in healing.

electrocardiogram (ECG) A graphic recording of the electrical current generated by the heart. The ECG provides information about cardiac dysrhythmias, myocardial ischemia, site and extent of myocardial infarction, cardiac hypertrophy, electrolyte imbalances, and effectiveness of cardiac drugs. It is a routine part of cardiovascular evaluation and is a valuable diagnostic test.

electroencephalography (EEG) A recording of the electrical activity of the cerebral hemispheres; it represents the voltage changes in various areas of the brain as determined by recording the difference between two electrodes.

electrolyte A substance in body fluids that carries an electrical charge; also called an "ion."

electromyography (EMG) A recording of the electrical activity of peripheral nerves by testing muscle activity.

electrophysiologic study (EPS) In cardiovascular assessment, an invasive procedure performed in a catheterization laboratory during which programmed electrical stimulation of the heart is used to induce and evaluate lethal dysrhythmias and conduction abnormalities to permit accurate diagnosis and effective treatment. The study is used in patients who have survived cardiac arrest, have recurrent tachydysrhythmias, or experience unexplained syncopal episodes.

electrovaporization of the prostate (EVAP) Procedure for treating benign prostatic hyperplasia with high-frequency electrical current to cut and vaporize excess tissue.

emboli (1) Tumor pieces that spread to distant body areas; (2) small blood clots that can enter circulation.

embolic protection device (EPD) A device that is placed beyond the stenosis during an angioplasty/stenting procedure to catch debris that breaks off during the procedure.

embolus The occurrence of inflammation and thickening of the vein wall around a clot (thrombus).

emergence Recovery from anesthesia.

emergency medical technician (EMT) Pre-hospital care provider who supplies basic life-support interventions such as oxygen, basic wound care, splinting, spinal immobilization, and monitoring of vital signs.

emergency medicine physician A member of the emergency health care team with education and training in the specialty of emergency patient management.

emergency operations center (EOC) A designated location in the Hospital Incident Command System (HICS) with accessible communication technology; also called the "command center."

emergency preparedness A goal or plan to meet the extraordinary need for hospital beds, staff, drugs, personal protective equipment, supplies, and medical devices such as mechanical ventilators.

Emergency Severity Index (ESI) A standardized model for triage that categorizes both patient acuity and resource utilization into five levels, from most urgent to least urgent.

emergent triage In a three-tiered triage scheme, the category that includes any condition or injury that poses an immediate threat to life or limb, such as crushing chest pain or active hemorrhage.

emetogenic A substance that induces nausea and vomiting.

emission The first stage of the male orgasm in which the prostate gland secretes its fluid at the same time as the vas deferens.

emmetropia The state of perfect refraction of the eye; with the lens at rest, light rays from a distant source are focused into a sharp image on the retina.

emotional abuse The intentional use of threats, humiliation, intimidation, and isolation to another person.

emotional lability Having uncontrollable emotions; for example, the patient laughs and then cries unexpectedly for no apparent reason.

empyema A collection of pus in the pleural space.

encephalitis An inflammation of the brain parenchyma (brain tissue) and meninges that affects the cerebrum, brainstem, and cerebellum; usually caused by a virus.

endogenous Originating inside the body.

endometrial ablation Procedure for dysfunctional uterine bleeding that removes a built-up uterine lining using a laser, roller ball, or balloon.

endometrial cancer Cancer of the inner uterine lining.

endometriosis The abnormal occurrence of endometrial tissue outside the uterine cavity.

endometritis An infection of the endometrium.

endorphins Morphine-like substances in the body that are released when the large-diameter nerve fibers are stimulated. They close the gate and decrease pain transmission.

endoscope A tube that allows viewing and manipulation of internal body areas.

endoscopic retrograde cholangiopancreatography (ERCP) The visual and radiographic examination of the liver, gallbladder, bile ducts, and pancreas by means of an endoscope and the injection of radiopaque dye to identify the cause and location of obstruction.

endoscopic variceal ligation (EVL) The application of small “O” bands around the base of the esophageal varices to cut off their blood supply; also called “banding.”

endoscopy The direct visualization of the gastrointestinal tract by means of a flexible fiberoptic endoscope.

endothelin A secretion produced by the endothelial cells when they are stretched.

endotoxin Any toxic substance that is produced in the cell walls of certain bacteria and released only with cell lysis. Typhoid and meningococcal diseases are caused by endotoxins.

endovascular stent graft The repair of an abdominal aortic aneurysm using a stent made of flexible material; the stent is inserted through a skin incision into the femoral artery by way of a catheter-based system.

endoventricular circular patch cardioplasty In the patient with heart failure, a procedure in which the surgeon removes portions of the cardiac septum and left ventricular wall and grafts a circular patch (synthetic or autologous) into the opening. This procedure provides a more normal shape to the left ventricle to improve hemodynamics.

end-stage kidney disease (ESKD) Acute renal failure combined with chronic renal insufficiency, resulting in the inability of the kidney to excrete waste products normally. The patient may need hemodialysis or a kidney transplant.

energy conservation Strategies to reduce the fatigue associated with chronic and disabling conditions, such as allowing rest periods and setting priorities.

engraftment The successful transplantation of cells in the patient's bone marrow.

enophthalmos Backward displacement of the eyeball into the orbit so that the eye appears sunken.

enteroscopy Visualization of the small intestine.

enterostomal feeding tube A tube used for patients who need long-term enteral feeding; the physician directly accesses the gastrointestinal tract using surgical, endoscopic, and laparoscopic techniques.

entropion The turning inward of the eyelid, causing the eyelashes to rub against the eye.

enucleation The surgical removal of the entire eyeball.

envenomation Venom injection from a snake bite.

epididymectomy Surgical excision of the epididymis from the testicle.

epididymis The cordlike structure along the posterior border of the testis; it is the first portion of a ductal system that transports sperm from the testes to the urethra.

epididymitis Inflammation of the epididymis.

epidural Term for the space between the dura mater and vertebrae; it consists of fat, connective tissue, and blood vessels.

epidural analgesia The instillation of a pain-blocking agent into the epidural space

(between the dura mater and the vertebral column).

epidural catheter A transducer or sensor that is placed between the skull and the dura (leaving the dura intact) to monitor intracranial pressure.

epidural hematoma An accumulation of clotted blood resulting from arterial bleeding into the space between the dura and the skull; a neurosurgical emergency.

epidural hemorrhage Arterial bleeding into the space between the dura and the skull.

epiglottis A leaf-shaped, elastic structure that is attached along one edge to the top of the larynx; it closes over the glottis during swallowing to prevent food from entering the trachea and opens during breathing and coughing.

epilepsy A chronic disorder characterized by recurrent, unprovoked seizure activity; may be caused by an abnormality in electrical neuronal activity, an imbalance of neurotransmitters, or a combination of both.

epiphyses The two knoblike ends of a long bone.

epistaxis Nosebleed.

epitympanum The upper portion of the tympanic cavity; a compartment containing the three bony ossicles.

equianalgesic Refers to the dose and route of administration of one drug that produces approximately the same degree of analgesia as the given dose and route of another drug.

equilibrium (1) A state of balance; (2) a condition in which there is no hydrostatic pressure difference between the two fluid spaces on either side of a permeable membrane.

erectile dysfunction (ED) The inability to achieve or maintain a penile erection sufficient for sexual intercourse.

ergonomics An applied science in which the workplace is designed to increase worker comfort (thus reducing injury) while increasing efficiency and productivity.

erosion Ulceration.

eructation The act of belching.

erythema Redness of the skin.

erythema migrans A round or oval flat or slightly raised rash.

erythrocyte A red blood cell. Red blood cells are the major cells in the blood and are responsible for tissue oxygenation.

erythroplakia A velvety red mucosal lesion, most often occurring in the oral cavity.

erythroplasia Red, velvety patches on a mucous membrane.

erythropoiesis The selective maturation of stem cells into mature erythrocytes.

eschar The crust of dead tissue that forms from coagulated particles of destroyed dermis in a patient with a full-thickness burn injury.

escharotomy Incision made through tight eschar to relieve pressure and allow normal blood flow and breathing.

esophageal stricture Narrowing of the esophageal opening.

esophageal varices The distention of fragile, thin-walled esophageal veins due to increased

pressure; the increased pressure is a result of portal hypertension, in which the blood backs up from the liver and enters the esophageal and gastric vessels that carry it into the systemic circulation.

esophagectomy The surgical removal of all or part of the esophagus.

esophagitis Inflammation of the esophagus.

esophagogastroduodenoscopy (EGD) The visual examination of the esophagus, stomach, and duodenum by means of a fiberoptic endoscope.

esophagogastrostomy The surgical creation of a communication between the stomach and the esophagus; it involves the removal of part of the esophagus and proximal stomach.

esophagomyotomy A surgical procedure in which the lower esophageal sphincter is incised to facilitate the passage of food for patients with achalasia.

essential hypertension Elevated blood pressure that is not caused by a specific disease. The major risk factor is a family history of hypertension; also called “primary hypertension.”

ethnopharmacology The study of how ethnicity affects how drugs work in the body, including drug absorption, distribution, metabolism, and excretion.

euploid Having the correct number of chromosome pairs for the species.

euploidy The normal diploid number for a cell.

eustachian tube Tube that connects the nasopharynx with the middle ear and opens during swallowing to equalize pressure within the middle ear.

euthyroid Having normal thyroid function.

evidence-based practice Care that nurses provide that is based on research and identified standards and considers the patient's preferences and values and the nurse's clinical expertise.

evisceration The total separation of all layers of a wound and the protrusion of internal organs through the open wound.

evoked potentials Tests to measure the electrical signals to the brain generated by hearing, touch, or sight; also called “evoked response.”

exacerbate To increase in severity of disease or its symptoms.

exacerbation An increase in severity of a disease; also called “flare-up.”

excision Removal of a lesion and local surrounding tissue.

excitability The ability of a cell to respond to a stimulus by initiating an impulse; also called “depolarization.” In cardiac electrophysiology, it is the ability of non-pacemaker myocardial cells to respond to an electrical impulse generated from pacemaker cells and to depolarize.

exercise electrocardiography In cardiovascular assessment, a test that assesses cardiovascular response to an increased workload; also called “exercise tolerance” or a “stress test.” Exercise electrocardiography helps determine the functional capacity of the heart, screens for coronary artery disease, and identifies

dysrhythmias that develop during exercise. It also aids in evaluating the effectiveness of anti-dysrhythmic drugs.

exertional dyspnea Breathlessness or difficulty breathing that develops during activity or exertion.

exertional heat stroke A form of heat stroke with a sudden onset, typically due to strenuous physical activity in hot, humid conditions. Lack of acclimatization to hot weather and wearing clothing too heavy for the environment are common contributing factors.

exogenous Originating outside the body.

exogenous hyperthyroidism Hyperthyroidism caused by excessive use of thyroid replacement hormones.

exophthalmos Abnormal protrusion of the eyeball (proptosis).

exotoxin Any toxic substance that is produced and released by certain bacteria into the surrounding environment. Botulism, tetanus, and diphtheria are attributed to exotoxins.

expedited partner therapy (EPT) Therapy used to treat chlamydia in which patients are given a drug or prescription with specific instructions for administration to their partners without direct evaluation by a health care provider; also called “patient-delivered partner therapy.”

exploratory laparotomy A surgical opening of the abdominal cavity to investigate the cause of an obstruction or peritonitis.

exposure (1) The final component of the primary survey that allows for thorough assessment of the trauma patient; (2) in radiation therapy, the amount of radiation that is delivered to a tissue.

expressed gene When a particular gene has been “turned on.”

expression (gene) The selective activation of a particular gene in a specific cell type.

expressive aphasia A type of aphasia resulting from damage in Broca’s area of the frontal lobe of the brain. A motor speech problem in which the patient understands what is said but is unable to communicate verbally and has difficulty writing; rote speech and automatic speech, such as responses to a greeting, are often intact. The patient is aware of the deficit and may become frustrated and angry. Also called “Broca’s aphasia” or “motor aphasia.”

expressivity In genetics, the degree of expression a person has when a specific autosomal dominant gene is present. The gene is always expressed, but some people have more severe results.

external catheter An epidural catheter, a portion of which exits the skin.

external fixation A system in which pins or wires are passed through skin and bone and connected to a rigid external frame to immobilize a fracture during healing.

external hemorrhoid A hemorrhoid that lies below the anal sphincter and can be seen on inspection of the anal region.

external otitis A painful irritation or infection of the skin of the external ear, with resulting allergic response or inflammation. When

it occurs in patients who participate in water sports, external otitis is called “swimmer’s ear.”

external urethral sphincter The sphincter composed of the skeletal muscle that surrounds the urethra.

extracapsular Located outside the joint capsule.

extracellular fluid (ECF) The portion of total body water (about one third) that is in the space outside the cells. This space also includes interstitial fluid, blood, lymph, bone, and connective tissue water, and the transcellular fluids.

extracranial-intracranial bypass A surgical procedure in which the surgeon performs a craniotomy and bypasses the blocked artery by making a graft (bypass) from the first artery to the second artery to establish blood flow around the blocked artery and re-establish blood flow to the involved areas.

extramedullary tumor A tumor found within the spinal dura but outside the cord.

extrapulmonary Involving nonpulmonary tissues.

extravasation Escape of fluids or drugs into the subcutaneous tissue; a complication of intravenous infusion.

extrinsic factor In hematology, an event (e.g., trauma) that occurs outside the blood to cause platelet plugs to form.

extubation The removal of an endotracheal tube.

exudate Pus.

F

facial paralysis See *Bell’s palsy*.

facilitated diffusion Diffusion across a cell membrane that requires the assistance of a transport system or membrane-altering system; also called “facilitated transport.”

facilitated transport See *facilitated diffusion*.

failed back surgery syndrome (FBSS) A combination of organic, psychological, and socioeconomic factors in patients for whom back surgery is not successful. Discouraged by repeated surgical procedures, these patients must continue long-term nonsurgical management of pain, including nerve blocks.

fall An unintentional change in body position that results in the patient’s body coming to rest on the floor or ground.

fallophobia In some older adults, the fear of falling and sustaining a serious injury.

fallopian tubes The tubes that insert into the fundus of the uterus, extending laterally close to the ovaries, and provide a duct between the ovaries and uterus for the passage of ova and sperm; also called “uterine tubes.”

far point of vision The farthest point at which the eye can see an object.

fascia An inelastic tissue that surrounds groups of muscles, blood vessels, and nerves in the body.

fasciculation Abnormal, involuntary twitching of a muscle.

fasciotomy A surgical procedure in which an incision is made through the skin and subcutaneous tissues into the fascia of the affected

compartment to relieve the pressure in and restore circulation to the affected area in the patient with acute compartment syndrome.

fat embolism syndrome (FES) A serious complication, usually resulting from a fracture, in which fat globules are released from the yellow bone marrow into the bloodstream. This syndrome usually occurs within 48 hours of the fracture and can result in respiratory failure or death, often from pulmonary edema.

fatigue (stress) fracture A fracture that results from excessive or repeated strain and stress on a bone.

fatty liver (steatosis) Caused by the accumulation of fats in and around the hepatic cells. It may be caused by alcohol abuse or other factors.

fecal occult blood test (FOBT) A diagnostic test that measures the presence of blood in the stool from gastrointestinal bleeding; this is a common finding associated with colorectal cancer.

Felty’s syndrome The combination of rheumatoid arthritis, hepatosplenomegaly (enlarged liver and spleen), and leukopenia.

femoral hernia A hernia that protrudes through the femoral ring.

fetor hepaticus The distinctive fruity or musty breath odor of chronic liver disease and portal-systemic encephalopathy.

fibrinolysis The breakdown of a clot.

fibrinolytic Drug that targets the fibrin component of the coronary thrombosis; used to dissolve thrombi in the coronary arteries and restore myocardial blood flow; examples include tissue plasminogen activator, anisoylated plasminogen-streptokinase activator complex, and reteplase.

fibroadenoma A solid, slowly enlarging, benign mass of connective tissue that is unattached to the surrounding breast tissue and is typically discovered by the patient herself. The mass is usually round, firm, easily movable, nontender, and clearly delineated from the surrounding tissue.

fibrocystic breast condition (FBC) Physiologic nodularity of the breast that is thought to be caused by an imbalance in the normal estrogen-to-progesterone ratio. It is the most common breast problem of women between 20 and 30 years of age.

fibrogenic Originating from fibrous tissue.

fibroids See *leiomyomas*.

fibromyalgia syndrome (FMS) A chronic pain syndrome characterized by pain and tenderness at specific sites in the back of the neck, upper chest, trunk, low back, and extremities along with fatigue, sleep disturbances, and headache.

fibrosis Replacement of normal cells with connective tissue and collagen (scar tissue).

filter The movement of fluid from the space with higher hydrostatic pressure through the membrane into the space with lower hydrostatic pressure.

filtration The movement of fluid through a cell or blood vessel membrane because of

hydrostatic pressure differences on both sides of the membrane.

financial abuse Mismanagement or misuse of the patient's property or resources.

first intention healing Healing in which the wound can be easily closed and dead space eliminated without granulation, which thus shortens the phases of tissue repair. Inflammation resolves quickly, and connective tissue repair is minimal, resulting in a thin scar.

fistula An abnormal opening between two adjacent organs or structures.

five cardinal manifestations of inflammation Warmth, redness, swelling, pain, and decreased function.

fixed occlusion Wiring the jaws together in the mouth closed position.

flaccid bladder See *areflexic bladder*.

flaccid paralysis Paralysis of a part of the body that is characterized by loss of muscle tone due to hypotonia; may be seen in the patient who has experienced a brain attack.

flail chest Inward movement of the thorax during inspiration, with outward movement during expiration; results from multiple rib fractures caused by blunt chest trauma that leaves a segment of the chest wall loose.

flatulence The presence of an excessive amount of gas in the stomach or intestines.

fluid overload An excess of body fluid. Also called "overhydration."

folliculitis A superficial bacterial infection involving only the upper portion of the hair follicle.

forced expiratory volume in the first second (FEV₁) Volume of air blown out as hard and fast as possible during the first second of the most forceful exhalation after the greatest full inhalation.

forced vital capacity (FVC) Volume of air exhaled from full inhalation to full exhalation.

forensic nurse examiner Emergency department specialist who is trained to recognize evidence of abuse and to intervene on the patient's behalf and who obtains patient histories, collects forensic evidence, and offers counseling and follow-up care for victims of rape, child abuse, and domestic violence.

fracture A break or disruption in the continuity of a bone.

frameshift mutation A mutation that occurs as a result of adding or deleting a single base or a group of bases.

fremitus Vibration.

frequency (1) The highness or lowness of tones (expressed in hertz). The greater the number of vibrations per second, the higher the frequency (pitch) of the sound; the fewer the number of vibrations per second, the lower the pitch; (2) an urge to urinate frequently in small amounts.

fresh frozen plasma (FFP) Plasma that is frozen immediately after donation so that the clotting factors are preserved.

friable Easily crumbled or damaged.

frostbite A cold injury characterized by the degree of tissue freezing and the resultant

damage it produces. Frostbite injuries can be superficial, partial, or full thickness.

frostnip A form of superficial frostbite (typically on the face, fingers, or toes) that produces pain, numbness, and pallor but is easily remedied with the application of warmth and does not induce tissue injury.

full agonist Morphine-like opioid analgesic that binds to mu receptors and blocks the release of substance P, preventing the transmission of pain; the most potent of all analgesics.

Fulmer SPICES A framework that identifies six serious "marker conditions" that can lead to longer hospital stays for patients, higher medical costs, and deaths.

fulminant hepatitis A severe acute and often fatal form of hepatitis caused by failure of the liver cells to regenerate, with progression to necrosis.

fundoplication A procedure in which the fundus of the stomach is wrapped around the lower end of the esophagus to anchor it and reinforce the lower esophageal sphincter; the most common surgical technique for hiatal hernia repair. A laparoscopic Nissen fundoplication is one variation of this type of procedure; a traditional, open surgical approach (using a large abdominal incision) is another variation.

furuncle A localized inflammation of the skin caused by bacterial infection, usually *Staphylococcus*, of a hair follicle; also called "a boil."

G

G₁ phase Phase of cell division in which the cell gets ready for division by taking on extra nutrients, making more energy, growing extra membrane, and increasing the amount of cytoplasm.

G₂ phase Phase of cell division in which the cell makes proteins that will be used in actual cell division and in normal physiologic function after cell division is complete.

gallium scan A test that is similar to the bone scan but uses the radioisotope *gallium citrate* and is more specific and sensitive in detecting bone problems. This substance also migrates to brain, liver, and breast tissue and therefore is used to examine these structures when disease is suspected.

gamma globulin See *immunoglobulin*.

ganglion A round, cystlike lesion, often overlying a wrist joint or tendon.

gas bloat syndrome A common, usually temporary, complication of fundoplication surgery. In this syndrome, patients are unable to voluntarily eructate (belch).

gastrectomy The surgical removal of part or all of the stomach.

gastric bypass (Roux-en-Y gastric bypass) A type of gastric restriction surgery in which gastric resection is combined with malabsorption surgery. The patient's stomach, duodenum, and part of the jejunum are bypassed so that fewer calories can be absorbed.

gastric lavage Procedure of irrigating the stomach in which a large-bore nasogastric

tube is inserted into the stomach and room-temperature solution is instilled in volumes of 200 to 300 mL. The solution and blood are repeatedly withdrawn manually until returns are clear or light pink and without clots.

gastrinoma A non-β cell islet tumor of the pancreas; the usual cause of Zollinger-Ellison syndrome.

gastritis An inflammation of the gastric mucosa (stomach lining).

gastroenteritis An increase in the frequency and water content of stools or vomiting as a result of inflammation of the mucous membranes of the stomach and intestinal tract. It affects primarily the small bowel and can be of either viral or bacterial origin.

gastroesophageal reflux disease (GERD) An upper gastrointestinal disease caused by the backward flow (reflux) of gastrointestinal contents into the esophagus.

gastrojejunostomy Surgical anastomosis of the stomach to the jejunum.

gastroparesis Delay in gastric emptying.

gastrostomy A stoma created from the abdominal wall into the stomach.

gate control theory A theory to explain the observed relationship between pain and emotion; a gating mechanism occurs in the spinal cord. Nerve fibers (A delta and C fibers) transmit pain impulses from the periphery of the body. The impulses travel to the dorsal horns of the spinal cord, specifically to the *substantia gelatinosa*. The cells of the *substantia gelatinosa* can inhibit or facilitate the pain impulses transmitted to the trigger cells (T-cells). When T-cell activity is inhibited, the gate is closed and impulses are less likely to be transmitted to the brain. When the gate is opened, pain impulses ascend to the brain.

gel phenomenon In patients with rheumatoid arthritis, morning stiffness that lasts between 45 minutes and several hours after awakening.

gene The deoxyribonucleic acid (DNA) in the form of chromosomes within the nucleus of each cell that contains the instructions for making all the different proteins any organism makes. Every human cell with a nucleus contains the entire set of human genes.

general anesthesia A reversible loss of consciousness induced by inhibiting neuronal impulses in the central nervous system.

generalized seizure One of the three broad categories of seizure disorders along with partial seizures and unclassified seizures. There are six types: tonic-clonic, tonic, clonic, absence, myoclonic, and atonic (akinetic).

generation time The time it takes one cell to divide into two cells.

genetics The science concerned with the general mechanisms of heredity and the variation of inherited traits.

genital herpes (GH) An acute, recurring, incurable viral disease of the genitalia caused by the herpes simplex virus and transmitted through contact with an infected person. An outbreak typically is preceded by a tingling sensation of the skin followed by the

appearance of vesicles (blisters) on the penis, scrotum, vulva, perineum, vagina, cervix, or perianal region. The blisters rupture spontaneously, leaving painful erosions. After the lesions heal, the virus remains dormant, periodically reactivating with a recurrence of symptoms.

genome The complete set of human genes. Each human cell with a nucleus contains the entire set of human genes. The human genome contains about 35,000 individual genes.

genomics The science focusing on the function of all of the human DNA, including genes and noncoding DNA regions.

genomic health care The application of known genetic variation to enhance health care to individuals and their families.

genotype The actual alleles for a genetic trait, not just what can be observed.

genu valgum A deformity in which the knees are abnormally close together and the space between the ankles is increased; also called “knock-knee.”

genu varum A deformity in which the knees are abnormally separated and the lower extremities are bowed inward; also called “bowleg.”

Geriatric Depression Scale—Short Form A valid and reliable screening tool to help determine if an older patient has clinical depression.

geriatric failure to thrive (GFTT) A complex syndrome including under-nutrition, impaired physical functioning, depression, and cognitive impairment.

Ghon tubercle A mass of necrotic lung tissue, visible on x-ray, that is the primary lesion of tuberculosis.

ghrelin The “hunger hormone” that is secreted in the stomach; increases in a fasting state and decreases after a meal.

Glasgow Coma Scale An objective and widely accepted tool for neurologic assessment and documentation of level of consciousness. It establishes baseline data for eye opening, motor response, and verbal response. The patient is assessed and assigned a numerical score for each of these areas. A score of 15 represents normal neurologic functioning, and a score of 3 represents a deep coma state.

glaucoma A group of ocular diseases resulting in increased intraocular pressure, causing reduced blood flow to the optic nerve and retina and followed by tissue damage.

glomerulus A series of specialized capillary loops that receive blood from the afferent arteriole and then filter water and small particles from the blood to make urine. The remaining blood leaves the glomerulus via the efferent arteriole.

glossectomy The partial or total surgical removal of the tongue.

glossitis A smooth, beefy red tongue.

glottis The opening between the true vocal cords inside the larynx.

glucagon A hormone secreted by the pancreas that increases blood glucose levels. It is a

“counterregulatory” hormone that has actions opposite those of insulin. It causes the release of glucose from cell storage sites whenever blood glucose levels are low.

gluconeogenesis The conversion of proteins and amino acids to glucose in the body.

glucosamine A supplement that may decrease inflammation.

glycemic A term referring to blood glucose.

glycogenesis The production of glycogen in the body.

glycogenolysis The breakdown of glycogen into glucose.

glycoprotein IIa/IIIb inhibitors Drugs that target the platelet component of the thrombus. They are administered intravenously to prevent fibrinogen from attaching to activated platelets at the site of a thrombus and are given to patients with acute coronary syndromes (especially unstable angina and non-Q-wave myocardial infarction). Examples include abciximab, eptifibatide, and tirofiban.

“go bag” See *personal readiness supplies*.

goiter Enlargement of the thyroid gland.

gonadotropins Hormones that stimulate the ovaries and testes to produce sex hormones.

gonads The male and female reproductive endocrine glands. Male gonads are the testes, and female gonads are the ovaries.

goniometer An instrument for measuring angles; also refers to a tool used to measure joint range of motion.

good death A death that is free from avoidable distress and suffering for patients, families, and caregivers; in agreement with patients’ and families’ wishes; and consistent with clinical practice standards.

gout A systemic disease in which urate crystals deposit in the joints and other body tissues, causing inflammation.

gradient A graded difference of hydrostatic pressure in a state of disequilibrium; that is, one fluid space has a higher hydrostatic pressure than the other.

grading System of classifying cellular aspects of a cancer tumor.

granulation The formation of scar tissue for wound healing to occur.

granulocyte Neutrophil that contains a large number of granules.

granuloma Growth that develops in the lungs of patients with sarcoidosis and contains lymphocytes, macrophages, epithelioid cells, and giant cells; scar tissue.

granuloma inguinale An ulcerative disease of the genital area that appears as a painless nodule.

Graves’ disease Toxic diffuse goiter characterized by hyperthyroidism, enlargement of the thyroid gland, abnormal protrusion of the eyes, and dry, waxy swelling of the front surfaces of the lower legs.

gray (gy) Unit of measurement for an absorbed radiation dose.

gray matter In the spinal cord, neuron cell bodies.

grief The emotional feeling related to the perception of loss.

grommet A polyethylene tube that is surgically placed through the tympanic membrane to allow continuous drainage of middle-ear fluids in the patient with otitis media.

ground substance A lubricant composed of protein and sugar groups that surrounds the dermal cells and fibers and contributes to the skin’s normal suppleness and turgor.

guardian A person appointed to make health care decisions for a patient who is determined to not be legally competent.

guided imagery An alternative therapy technique in which the patient is provided with images or prompts by a nurse, family member, or friend or via a tape.

Guillain-Barré syndrome (GBS) An acute autoimmune disorder characterized by varying degrees of motor weakness and paralysis. It may be referred to by a variety of other names, such as “acute idiopathic polyneuritis” and “polyradiculoneuropathy.”

gynecomastia Abnormal enlargement of the breasts in men.

H

H₂-receptor antagonists A group of drugs that inhibit gastric acid secretion by blocking the effects of histamine on parietal cell receptors in the stomach.

halitosis A foul odor of the mouth.

hallucinogens Chemical substances that possess mind-altering or perception-altering properties, such as lysergic acid (LSD), phenylcyclidine (PCP), and marijuana.

hallux valgus A common deformity of the foot that occurs when the great toe deviates laterally at the metatarsophalangeal joint; sometimes referred to as a “bunion.”

halo fixator A static traction device used for immobilization of the cervical spine. Four pins or screws are inserted into the skull, and a metal halo ring is attached to a plastic vest or cast when the spine is stable, allowing increased patient mobility.

hammertoe The dorsiflexion of any metatarsophalangeal joint with plantar flexion of the adjacent proximal interphalangeal joint. The second toe is most often affected.

hand hygiene Infection control protocol that refers to both handwashing and alcohol-based hand rubs.

handwashing The process of wetting, soaping, lathering, applying friction under running water for at least 15 seconds, rinsing, and drying the hands; an important part of infection control.

health care-acquired infections (HAIs) Infections that are associated with the provision of health care; for example, microorganisms can enter the body through the genitourinary tract in patients with indwelling urinary catheters.

Healthy People 2020 A program created by the U.S. Department of Health and Human Services with the goal of eliminating differences in health status among racial and ethnic minorities while continually improving the overall health of all Americans through

research, preventive programs, and inclusion of members of minority groups.

heart failure A general term for the inadequacy of the heart to pump blood throughout the body, causing insufficient perfusion of body tissues with vital nutrients and oxygen; also called “pump failure.”

heart rate (HR) Term referring to the number of times the ventricles contract each minute.

heart reduction surgery Partial left ventriculectomy; in the patient with heart failure, a surgical procedure to remove a triangle-shaped section of the weakened heart in the left lateral ventricle to reduce the ventricle's diameter and decrease wall tension.

heart transplantation A surgical procedure in which a heart from a donor with a comparable body weight and ABO compatibility is transplanted into a recipient less than 6 hours after procurement. It is the treatment of choice for patients with severe dilated cardiomyopathy and may be considered for patients with restrictive cardiomyopathy.

heat exhaustion A syndrome primarily caused by dehydration from heavy perspiration and inadequate fluid and electrolyte consumption during heat exposure over hours to days; if left untreated, can be a precursor to heat stroke.

heat stroke A true medical emergency in which the victim's heat regulatory mechanisms fail and are unable to compensate for a critical elevation in body temperature; if uncorrected, organ dysfunction and death will ensue.

Heberden's nodes Swelling at the distal interphalangeal joints in osteoarthritis that involves the hands.

helminths Parasitic worms that are capable of causing infectious disease with gastrointestinal symptoms in humans. The three general categories are roundworms (nematodes), flukes (trematodes), and tapeworms (cestodes).

hematemesis The vomiting of blood.

hematochezia The passage of red blood via the rectum.

hematocrit The percentage of packed red blood cells per deciliter of blood.

hematogenous Disseminated by the blood through the circulation.

hematogenous tuberculosis A form of tuberculosis that spreads throughout the body when a large number of organisms enter the blood. Also called “miliary tuberculosis.”

hematopoiesis The production of blood cells, which occurs in the red marrow of bones.

hematuria Blood in the urine.

hemianopsia Blindness in half of the visual field of one or both eyes; also called “hemianopia.”

hemiarthroplasty Surgical replacement of part of the shoulder joint, typically the humeral component, as an alternative to total shoulder arthroplasty.

hemiparesis Weakness on one side of the body.

hemiplegia Paralysis on one side of the body.

hemoconcentration Elevated plasma levels of hemoglobin, hematocrit, serum osmolality, glucose, protein, blood urea nitrogen, and electrolytes that occur when only the water is lost and other substances remain.

hemodilution Excessive water in the vascular space.

hemodynamic monitoring An invasive system that directly measures pressures in the heart and great vessels; used in critical care areas to provide quantitative information about vascular capacity, blood volume, pump effectiveness, and tissue perfusion.

hemoglobin A (HbA) Normal adult hemoglobin. The molecule has two alpha chains and two beta chains of amino acids.

hemolytic The characteristic of destroying red blood cells.

hemoptysis Coughing up blood or blood-stained sputum.

hemorrhoid Unnaturally swollen or distended vein in the anorectal region.

hemorrhoidectomy The excision of a hemorrhoid.

hemostasis The multi-step process of controlled blood clotting.

heparin-induced thrombocytopenia and thrombosis (HIT) The aggregation of platelets into “white clots” that can cause thrombosis, usually in the form of an acute arterial occlusion; occurs with heparin administration; also called “white clot syndrome.”

hepatic coma See *portal-systemic encephalopathy*.

hepatic encephalopathy See *portal-systemic encephalopathy*.

hepatitis The widespread inflammation of liver cells.

hepatitis A Hepatitis that is caused by the hepatitis A virus (HAV) and is characterized by a mild course similar to that of a typical viral syndrome and often goes unrecognized. It is spread via the fecal-oral route by oral ingestion of fecal contaminants. Sources of infection include contaminated water, shellfish caught in contaminated water, and food contaminated by infected food handlers. The virus may also be spread by oral-anal sexual activity. The incubation period is usually 15 to 50 days. The disease is usually not life threatening but may be more severe in people older than 40 years. It can also complicate pre-existing liver disease.

hepatitis B A form of hepatitis that is caused by the hepatitis B virus, which is shed in the body fluids of infected people and asymptomatic carriers. It is spread through unprotected sexual intercourse with an infected partner, needle sharing, blood transfusions, and other modes. Symptoms usually occur within 25 to 180 days of exposure and include nausea, fever, fatigue, joint pain, and jaundice. Most adults who get hepatitis B recover, clear the virus from their body, and develop immunity; however, up to 10% of patients with the disease do not develop immunity and become carriers.

hepatitis C Hepatitis that is caused by the hepatitis C virus. Transmission is blood to

blood, most commonly by needle sharing or needle stick injury with contaminated blood. The rate of sexual transmission is very low; it is not spread by casual contact and is rarely transmitted from mother to fetus. The average incubation period is 7 weeks. Most people are asymptomatic and are not diagnosed until long after the initial exposure when an abnormality is detected during a routine laboratory evaluation or when symptoms of liver impairment appear. Hepatitis C causes chronic inflammation in the liver that eventually causes the hepatocytes to scar and may progress to cirrhosis.

hepatitis carrier Person who has had hepatitis B but has not developed immunity. Hepatitis carriers can infect others even though they are not sick and demonstrate no obvious signs of disease. Chronic carriers are at high risk for cirrhosis and liver cancer.

hepatitis D The hepatitis D virus (HDV) co-infects with hepatitis B virus (HBV) and needs the presence of HBV for viral replication. HDV can co-infect a patient with HBV or can occur as a superinfection in a patient with chronic HBV. Superinfection usually develops into chronic HDV infection. The incubation period is 14 to 56 days. As with HBV, the disease is transmitted primarily by parenteral routes.

hepatitis E Hepatitis E virus (HEV) was originally identified by its association with waterborne epidemics of hepatitis in the Indian subcontinent. Since then, it has occurred in epidemics in Asia, Africa, the Middle East, Mexico, and Central and South America, typically after heavy rains and flooding. In the United States, hepatitis E has been found only in travelers returning from endemic areas. The virus is transmitted via the fecal-oral route, and the clinical course resembles that of hepatitis A. HEV has an incubation period of 15 to 64 days. There is no evidence at this time of a chronic form of hepatitis E.

hepatocyte Liver cell.

hepatomegaly Enlargement of the liver.

hepatorenal syndrome (HRS) A state of progressive oliguric renal failure associated with hepatic failure, resulting in functional impairment of kidneys with normal anatomic and morphologic features. It indicates a poor prognosis for the patient with hepatic failure and is often the cause of death in patients with cirrhosis.

herbal preparation Plant used for medicinal purposes.

hereditary chronic pancreatitis Pancreatitis that may be associated with *SPINK1* and *CFTR* gene mutations.

heritability The risk that a disorder can be transmitted to one's children in a recognizable pattern.

hernia A weakness in the abdominal muscle wall through which a segment of the bowel or other abdominal structure protrudes.

herniated nucleus pulposus (HNP) The protrusion (herniation) of the pulpy material from the center of a vertebral disk; herniated

disks occur most often between the fourth and fifth lumbar vertebrae (L4-5) but may occur at other levels. A herniation in the lumbosacral area can press on the adjacent spinal nerve (usually the sciatic nerve), causing severe burning or stabbing pain into the leg or foot, or it may press on the spinal cord itself, causing leg weakness and bowel and bladder dysfunction. The specific area of pain depends on the level of herniation.

hernioplasty Surgical repair of a hernia in which the surgeon reinforces the weakened outside muscle wall with a mesh patch.

herniorrhaphy The surgical repair of a hernia.

heterotopic ossification Abnormal bony overgrowth, often into muscle; seen as a complication of prolonged immobility in patients with spinal cord injury.

hiatal hernia Protrusion of the stomach through the esophageal hiatus of the diaphragm and into the thorax; also called “diaphragmatic hernia.”

high altitude Elevations above 5000 feet, which can produce a range of physiologic consequences in the body.

high altitude disease (HAD) Pathophysiologic responses in the body caused by exposure to low partial pressure of oxygen at high elevations.

high altitude pulmonary edema (HAPE) A form of acute mountain sickness often seen with high altitude cerebral edema. Clinical indicators include persistent dry cough, cyanosis of the lips and nail beds, tachycardia and tachypnea at rest, and rales auscultated in one or both lungs. Pink, frothy sputum is a late sign.

highly sensitive C-reactive protein (hsCRP) A serum marker of inflammation and a common and critical component to the development of atherothrombosis.

high-output heart failure Heart failure that occurs when cardiac output remains normal or above normal. It is usually caused by increased metabolic needs or hyperkinetic conditions such as septicemia (fever), anemia, and hyperthyroidism. This type of heart failure is different from left- and right-sided heart failure, which are typically low-output states, and is not as common as other types.

hilum The area of the kidney in which the renal artery and nerve plexus enter and the renal vein and ureter exit. This area is not covered by the renal capsule.

hirsutism Abnormal growth of body hair, especially on the face, chest, and the linea alba of the abdomen of women.

holistic care The connection and integration of the mind, body, and spirit.

homeopaths Care providers who plan individualized care by prescribing small doses of specially prepared plant and animal extracts and minerals to promote healing.

homeopathic medicine Practice of medicine that uses small doses of specially prepared plant extracts and minerals to promote healing.

homeostasis The narrow range of normal conditions (e.g., body temperature, blood

electrolyte values, blood pH, blood volume) in the human body; the tendency to maintain a constant balance in normal body states.

homeostatic mechanism A safeguard or control mechanism within the human body that prevents dangerous changes.

homocysteine An essential sulfur-containing amino acid that is produced when dietary protein breaks down; elevated values (greater than 15 mmol/L) may be a risk factor for the development of cardiovascular disease.

homonymous hemianopsia Condition in which there is blindness in the same side of both eyes.

hordeolum An infection of the sweat glands in the eyelid.

hormone Chemical produced in the body that exerts its effects on specific tissues known as “target tissues.”

hospice care An interdisciplinary approach to facilitate quality of life and a “good” death for patients near the end of their lives, with care provided in a variety of settings.

Hospital Incident Command System (HICS) An organizational model for disaster management in which roles are formally structured under the hospital or long-term care facility incident commander, with clear lines of authority and accountability for specific resources.

hospital incident commander As defined in a hospital’s emergency response plan, the person (either an emergency physician or administrator) who assumes overall leadership for implementing the institutional plan at the onset of a mass casualty incident. The hospital incident commander has a global view of the entire situation, facilitates patient movement through the system, and brings in resources to meet patient needs.

hospitalist Family practitioner or internist employed by a hospital.

Huber needle A noncoring port access needle used in central IV therapy.

human leukocyte antigen (HLA) Antigen that is present on the surfaces of nearly all body cells as a normal part of the person and acts as an antigen only if it enters another person’s body.

human papilloma virus (HPV) test A test that can identify many high-risk types of HPV associated with the development of cervical cancer.

humoral immunity A type of immunity provided by antibodies circulating in body fluids.

Huntington disease (HD) A hereditary disorder transmitted as an autosomal dominant trait at the time of conception (formerly called “Huntington chorea”). Men and women between 35 and 50 years of age are affected; clinical onset is gradual. The two main symptoms are progressive mental status changes (leading to dementia) and choreiform movements (rapid, jerky movements) in the limbs, trunk, and facial muscles.

hydrocephalus The abnormal accumulation of cerebrospinal fluid within the skull.

hydronephrosis Abnormal enlargement of the kidney caused by a blockage of urine lower in the tract and filling of the kidney with urine.

hydrophilic Tending to absorb water readily.

hydrophobic Not readily absorbing water; waterproof.

hydrostatic pressure The force of the weight of water molecules pressing against the confining walls of a space.

hydrotherapy The application of water for treatment of injury or disease.

hydroureter Abnormal distention of the ureters.

hyperacusis An intolerance for sound levels that do not bother other people.

hyperaldosteronism Excessive mineralocorticoid production.

hypercalcemia A total serum calcium level above 10.5 mg/dL or 2.75 mmol/L, which can cause fatigue, anorexia, nausea and vomiting, constipation, polyuria, and serious damage to the urinary system.

hypercapnia Increased arterial carbon dioxide levels.

hypercarbia Increased partial pressure of arterial carbon dioxide (Paco₂) levels.

hypercellularity An abnormal number of cells.

hyperemia Increased blood flow to an area.

hyperesthesia Abnormally increased sensation.

hyperextension A mechanism of injury that occurs when a part of the body is suddenly accelerated and then decelerated, causing extreme extension.

hyperflexion A mechanism of injury that occurs when a part of the body is suddenly and forcefully accelerated forward, causing extreme flexion.

hyperglycemia Abnormally high levels of blood glucose.

hyperglycemic-hyperosmolar state (HHS) State of increased blood osmolarity caused by hyperglycemia.

hyperinsulinemia Chronic high blood insulin levels.

hyperkalemia An elevated level of potassium in the blood.

hyperlipidemia An elevation of serum lipid (fat) levels in the blood.

hypermagnesemia A serum magnesium level above 2.1 mEq/L.

hypernatremia An excessive amount of sodium in the blood.

hyperopia An error of refraction that occurs when the eye does not refract light enough, causing images to fall (converge) behind the retina and resulting in poor near vision; also called “farsightedness.”

hyperosmotic Describes fluids with osmolarities (solute concentrations) greater than 300 mOsm/L; hyperosmotic fluids have a greater osmotic pressure than do isosmotic fluids and tend to pull water from the isosmotic fluid space into the hyperosmotic fluid space until an osmotic balance occurs. Also called “hypertonic.”

hyperphosphatemia A serum phosphorus level above 4.5 mg/dL.

hyperpituitarism Hormone oversecretion that occurs with pituitary tumors or hyperplasia.

hyperplasia Growth that causes tissue to increase in size by increasing the number of cells; abnormal overgrowth of tissue.

hyperpnea An abnormal increase in the depth of respiratory movements.

hypersensitivity An overreaction to a foreign substance.

hypertension A cardiovascular condition pertaining to people who have a systolic blood pressure of 140 mm Hg or higher or a diastolic blood pressure of 90 mm Hg or higher or who take medication to control blood pressure; approximately 1 of every 5 Americans has hypertension.

hyperthermia Elevated body temperature; fever.

hyperthyroidism A condition caused by excessive production of thyroid hormone.

hypertonia A condition of excessive muscle tone, which tends to cause fixed positions or contractures of the involved extremities and restricted range of motion of the joints.

hypertonic See *hyperosmotic*.

hypertriglyceridemia Elevated levels (150 mg/dL or above) of triglyceride in the blood.

hypertrophic cardiomyopathy (HCM) A type of cardiomyopathy that involves disarray of the myocardial fibers and asymmetric ventricular hypertrophy; leads to a stiff left ventricle that results in diastolic filling abnormalities.

hypertrophy The enlargement or overgrowth of an organ; tissue increases in size by the enlargement of each cell.

hyperuricemia An excess of uric acid in the blood.

hyperventilation A state of increased rate and depth of breathing.

hyperviscosity Excessively thick or concentrated, as of the blood.

hyperviscous The quality of being thicker than normal.

hypervolemia Increased plasma volume; or fluid excess.

hyphema A hemorrhage in the anterior chamber of the eye that occurs when a force is applied to the eye and breaks the blood vessels.

hypnosis An altered state of consciousness in which a person enters a trance and loses an overall sense of reality.

hypocalcemia A total serum calcium level below 9.0 mg/dL or 2.25 mmol/L.

hypocapnia Decreased arterial carbon dioxide levels.

hypodermoclysis The slow infusion of isotonic fluids into subcutaneous tissue.

hypoesthesia Abnormally decreased sensation.

hypoglycemia Abnormally low levels of glucose in the blood.

hypokalemia A decreased serum potassium level; a common electrolyte imbalance.

hypomagnesemia Decreased serum magnesium levels.

hyponatremia A serum sodium level below 136 mEq/L (mmol/L).

hypo-osmotic Describes fluids with osmolarities of less than 270 mOsm/L. Hypo-osmolar fluids have a lower osmotic pressure than isosmotic fluids, and water tends to be pulled from the hypo-osmotic fluid space into the isosmotic fluid space until an osmotic balance occurs. Also called "hypotonic."

hypoperfusion Decreased blood flow through an organ.

hypophonia Soft voice.

hypophosphatemia Inadequate levels of phosphate in the blood (below 3.0 mg/dL).

hypophysectomy Surgical removal of the pituitary gland.

hypoplasia Reduced production of cells.

hypoproteinemia A decrease in serum proteins.

hyporeflexia A decreased response to deep tendon reflex stimulation.

hyposthenuria The inability to form urine of high specific gravity; loss of urine-concentrating ability.

hypothalamic-hypophyseal portal system The small, closed circulatory system that the hypothalamus shares with the anterior pituitary gland, which allows hormones produced in the hypothalamus to travel directly to the anterior pituitary gland.

hypothalamus A structure within the brain; an integral part of autonomic nervous system control (controlling temperature and other functions) that is essential in intellectual function.

hypothermia A core body temperature less than 95° F (35° C).

hypotonia An abnormal condition of inadequate muscle tone, with an inability to maintain balance.

hypotonic See *hypo-osmotic*.

hypoventilation A state in which gas exchange at the alveolar-capillary membrane is inadequate so that too little oxygen reaches the blood and carbon dioxide is retained.

hypovolemia Abnormally decreased volume of circulating fluid in the body; fluid deficit.

hypoxemia (hypoxemic) Decreased blood oxygen levels; hypoxia.

hypoxia (hypoxic) A reduction of oxygen supply to the tissues.

hysterosalpingogram An x-ray of the cervix, uterus, and fallopian tubes that is performed after injection of a contrast medium. This test is used in infertility workups to evaluate tubal anatomy and patency and uterine problems such as fibroids, tumors, and fistulas.

hysteroscopy Examination of the interior of the uterus and cervical canal using an endoscope.

I

icterus Yellow discoloration of the sclerae.

idiopathic chronic pancreatitis Pancreatitis that may be associated with *SPINK1* and *CFTR* gene mutations.

idiopathic epilepsy See *primary epilepsy*.

idiopathic seizure See *unclassified seizure*.

idioventricular rhythm A heart rhythm in which the ventricular nodal cells pace the ventricles at a rate that is usually less than 40 beats/min; also called "ventricular escape rhythm."

ileostomy The surgical creation of an opening into the ileum, usually by bringing the end of the terminal ileum through the abdominal wall and forming a stoma, or ostomy.

imagery In complementary medicine, a mind-body therapy or form of distraction in which the patient is encouraged to visualize or think about some pleasant or desirable feeling, sensation, or event.

immediate memory Short-term or new memory. Test by asking the patient to repeat two or three unrelated words to make sure they were heard; after about 5 minutes, while continuing the examination, ask the patient to repeat the words.

immunity Resistance to infection; usually associated with the presence of antibodies or cells that act on specific microorganisms.

immunocompetence Full immunity, which requires the interaction of the processes of inflammation, antibody-mediated immunity (humoral immunity), and cell-mediated immunity.

immunocompetent Having proper functioning of the body's ability to maintain itself and defend against disease.

immunoglobulin Antibody; also called "gamma globulin."

impedance The pressure that the heart must overcome to open the aortic valve. The amount of impedance depends on aortic compliance and total systemic vascular resistance, a combination of blood viscosity and arteriolar constriction.

impedance cardiography (ICG) A noninvasive monitoring system that measures the total impedance (resistance) to the flow of electricity in the heart and provides measures of thoracic fluid, left ventricular function (cardiac output and cardiac index), preload, afterload, and contractility of the heart.

impermeable Not porous.

implanted port A device used for long-term or frequent infusion therapy; consists of a portal body, a dense septum over a reservoir, and a catheter that is surgically implanted on the upper chest or upper extremity.

inactivation The process of binding an antibody to an antigen to cover the antigen's active site and to make the antigen harmless without destroying it; also called "neutralization."

incisional hernia Protrusion of the intestine at the site of a previous surgical incision resulting from inadequate healing. Most often caused by postoperative wound infections, inadequate nutrition, and obesity.

incomplete spinal cord injury An injury in which the spinal cord has been damaged in a way that allows some function or movement below the level of the injury.

incontinence Involuntary loss of urine or stool severe enough to cause social or hygienic problems.

incus One of the three bony ossicles of the ear; also called the “anvil.”

independent living skills See *instrumental activities of daily living (IADLs)*.

independent nursing function A nursing function initiated and carried out by the nurse without direction from the health care provider.

indirect contact A mode of infection transmission in which microorganisms are transferred passively from a contaminated inanimate object to a susceptible person.

indirect inguinal hernia A sac formed from the peritoneum that contains a portion of the intestine or omentum. The hernia pushes downward at an angle into the inguinal canal. In males, indirect inguinal hernias can become large and often descend into the scrotum.

indolent Slow-growing.

induration Hardening.

infarction Necrosis, or cell death.

infective endocarditis A microbial infection (e.g., viruses, bacteria, fungi) involving the endocardium; previously called “bacterial endocarditis.”

inferior vena cava filtration Surgical procedure in which the surgeon inserts a filter device percutaneously into the inferior vena cava of a patient with recurrent deep vein thrombosis (to prevent pulmonary emboli) or pulmonary emboli that do not respond to medical treatment. The device is meant to trap emboli in the inferior vena cava before they progress to the lungs. Holes in the device allow blood to pass through, thus not significantly interfering with the return of blood to the heart.

inferior wall myocardial infarction A type of myocardial infarction that occurs in patients with obstruction of the right coronary artery, causing significant damage to the right ventricle.

infertility Difficulty becoming pregnant.

infiltrating ductal carcinoma The most common type of breast cancer; it originates in the mammary ducts and grows in the epithelial cells lining these ducts.

infiltration The leakage of IV solution into the tissues around the vein.

inflammatory breast cancer A rare but highly aggressive form of invasive breast cancer. Symptoms include swelling, skin redness, and pain in the breasts.

inflammatory cytokines Proteins produced primarily by white blood cells that assist in the inflammatory and immune responses of the body (e.g., tumor necrosis factor, interleukins).

inflow disease Chronic peripheral arterial disease with obstruction at or above the common iliac artery, abdominal aorta, or profunda femoris artery. The patient experiences discomfort in the lower back, buttocks, or thighs after walking a certain distance. The pain usually subsides with rest.

informatics A specialized computer science that involves using information and

technology to communicate, manage knowledge, mitigate error, and support decision making.

infrapatellar notch The area directly below the knee.

infratentorial Located below the tentorium of the cerebellum.

infusate A solution that is infused into the body.

infusion therapy The delivery of parenteral medications and fluids through a variety of catheter types and locations using multiple techniques and procedures, such as intravenous and intra-arterial therapy to deliver solutions into the vascular system.

inhalants Breathable chemical vapors that produce psychoactive effects.

initial First or, in phases of shock, early.

initiation In oncology, the first step in carcinogenesis; caused by damage to the genes.

innate-native immunity Also called “natural immunity”; a type of immunity that cannot be developed or transferred from one person to another and is not an adaptive response to exposure or invasion by foreign proteins.

inpatient A patient who is admitted to a hospital.

insensible water loss Water loss from the skin, lungs, and stool that cannot be controlled.

instrumental activities of daily living (IADLs) Special activities performed in the course of a day such as using the telephone, shopping, preparing food, and housekeeping. Also called “independent living skills.”

insufflation The practice of injecting gas or air into a cavity before surgery to separate organs and improve visualization.

insulin resistance A reduced ability of most cells to respond to insulin. It is associated with type 2 diabetes.

insulinoma A usually benign tumor of the islets of Langerhans that causes excessive insulin secretion and subsequent hypoglycemia (low serum glucose); the most common type of neuroendocrine pancreatic tumor, even though it is rare.

integrative medicine Practice of medicine that combines therapies from traditional Western medicine and complementary and alternative medicine (CAM).

intensity A quality of sound that is expressed in decibels; generally, having a high degree of energy or activity.

intensivist A physician who specializes in critical care.

intention tremor A tremor that occurs when performing an activity.

interbody cage fusion Cagelike spinal device that is implanted into the space where a disk was removed. Bone graft tissue grows into and around the cage and creates a stable spine at that level.

intercostally Located between the ribs.

interdisciplinary pain team Team typically consisting of one or more nurses, pharmacists, case managers, and physicians who consult with staff and prescribers on how best to

control the patient’s pain; also called “analgesia team.”

intermittent claudication A characteristic leg pain experienced by patients with chronic peripheral arterial disease. Typically, patients can walk only a certain distance before a cramping muscle pain forces them to stop. As the disease progresses, the patient can walk only shorter and shorter distances before pain recurs. Ultimately, pain may occur even at rest.

internal derangement A broad term for disturbances of an injured knee joint.

internal fixation The use of metal pins, screws, rods, plates, or prostheses to immobilize a fracture during healing. The surgeon makes an incision (open reduction) to gain access to the broken bone and implants one or more devices.

internal hemorrhoid A hemorrhoid that is located above the anal sphincter and cannot be seen on inspection of the perineal area.

internal urethral sphincter The smooth detrusor muscle that lines the interior of the bladder neck.

interstitial cystitis A bladder inflammation of unknown etiology that occurs predominantly in women and is characterized by urinary frequency and pain on bladder filling.

interstitial fluid A portion of the extracellular fluid that is between cells, sometimes called the “third space.”

interstitial laser coagulation (ILC) Procedure for treating benign prostatic hyperplasia that uses laser energy to coagulate excess tissue. Also called “contact laser prostatectomy (CLP).”

intra-abdominal hypertension (IAH) Condition of sustained or repeated intra-abdominal pressure of 12 mm Hg or higher.

intra-abdominal pressure Pressure contained within the abdominal cavity.

intra-aortic balloon pump (IABP) An intra-aortic counterpulsation device. It may be used as an invasive intervention to improve myocardial perfusion during an acute myocardial infarction, reduce preload and afterload, and facilitate left ventricular ejection. It is also used when patients do not respond to drug therapy with improved tissue perfusion, decreased workload of the heart, and increased cardiac contractility.

intra-arterial thrombolysis Therapy for brain attack that delivers the thrombolytic agent directly into the thrombus within 6 hours of the attack’s onset.

intracapsular Located within the joint capsule.

intracellular fluid (ICF) The portion of total body water (about two thirds) that is found inside the cells.

intracerebral hemorrhage Bleeding within the brain tissue caused by the tearing of small arteries and veins in the subcortical white matter.

intracorporeal Situated or occurring inside the body.

intractable pain Chronic pain that cannot be managed using standard therapies.

intramedullary tumor Tumor originating within the spinal cord in the central gray matter and anterior commissure. It is often malignant.

intraocular pressure (IOP) Pressure of the fluid within the eye; may be measured by methods that involve direct contact with the eye or by noncontact techniques.

intraoperative During surgery.

intraosseous (IO) therapy Infusion therapy that is delivered to the vascular network in the long bones.

intraperitoneal (IP) therapy The administration of antineoplastic agents into the peritoneal cavity.

intrapulmonary Within the respiratory tract.

intrarenal/intrinsic renal failure Decreased renal function resulting from damage to the glomeruli, interstitial tissue, or tubules. It can contribute to acute renal failure.

intrathecal Referring to the spine.

intrathecal (subarachnoid) analgesia The introduction of a pain-blocking agent into the space between the arachnoid mater and pia mater of the spinal cord (where the cerebrospinal fluid is located).

intravascular ultrasonography (IVUS) In cardiac catheterization, the use of a flexible catheter with a miniature transducer that emits sound waves. Sound waves are reflected off the plaque and the arterial wall, creating an image of the blood vessel; used as an alternative to injecting a contrast medium into the coronary arteries.

intravenous (systemic) fibrinolytic therapy The intravenous administration of thrombolytic agents to dissolve a thrombus.

intraventricular catheter (IVC) A small tube that is inserted into the anterior horn of the lateral ventricle of the nondominant cerebral hemisphere to monitor intracranial pressure; can also be used to drain cerebrospinal fluid to decrease pressure and obtain specimens for laboratory analysis.

intravesical Situated inside the bladder.

intrinsic factor A substance normally secreted by the gastric mucosa and needed for intestinal absorption of vitamin B₁₂. A deficiency of intrinsic factor and the resulting failure to absorb vitamin B₁₂ leads to pernicious anemia.

intussusception The telescoping of a segment of the intestine within itself.

invasive Pertaining to the ability to penetrate nearby tissue; said of cancers.

invasive temporary pacemaker A cardiac pacing system consisting of an external battery-operated pulse generator and pacing electrodes, or lead wires, that attach to the generator on one end and are in contact with the heart on the other end. Electrical pulses are emitted from the negative terminal of the generator, flow through a lead wire, and stimulate the cardiac cells to depolarize. The current seeks ground by returning through the other lead wire to the positive terminal of the generator, thus completing a circuitous route.

ion A substance found in body fluids that carries an electrical charge; also called "electrolyte."

iontophoresis A treatment for lower back pain in which a small electrical current and dexamethasone are typically used.

ipsilateral Occurring on the same side.

iris The colored portion of the external eye; its center opening is the pupil. Muscles of the iris contract and relax to control pupil size and the amount of light entering the eye.

iritis Inflammation of the iris.

irreducible hernia A hernia that cannot be reduced or placed back into the abdominal cavity; requires immediate surgical evaluation.

irreversible stage The former name for the refractory stage of shock. See *refractory stage*.

irritability An overresponse to stimuli.

irritable bowel syndrome (IBS) A chronic gastrointestinal disorder characterized by chronic or recurrent diarrhea, constipation, and/or abdominal pain and bloating; also called "spastic colon," "mucous colon," or "nervous colon."

ischemia Blockage of blood flow through a blood vessel. Prolonged severe ischemia can cause irreversible damage to tissue.

ischemic Cell dysfunction or death from a lack of oxygen resulting from decreased blood flow in a body part.

ischemic stroke A type of brain attack caused by occlusion of a cerebral artery by either a thrombus or an embolus. About 80% of all brain attacks are ischemic.

Ishihara chart The most commonly used tool for testing color vision. The chart shows numbers composed of dots of one color within a circle of dots of a different color. Each eye is tested separately by asking the patient what numbers he or she sees on the chart; reading the numbers correctly indicates normal color vision.

isoelectric Having equal electric potentials, such as in the heart.

isosmotic Having the same osmotic pressures; also called "isotonic" or "normotonic."

isosthenuria Excretion of urine with the same osmolality as that of plasma; occurs in patients with declining renal function due to chronic renal failure.

isotonic See *isosmotic*.

isotope A different form of a specific element; has a slightly different atomic weight and number of neutrons.

"itch-scratch-itch" cycle A pattern seen in patients with pruritus who try to relieve the itching sensation by scratching the skin, further stimulating the itch receptors and causing the itching sensation to continue.

J

jaundice A syndrome characterized by excessive circulating bilirubin levels. Liver cells cannot effectively excrete bilirubin, and skin and mucous membranes become characterized by a yellow coloration.

jejunostomy The surgical creation of an opening between the jejunum and the surface of the abdominal wall.

joint The place at which two or more bones come together; also referred to as "articulation" of the joint. The primary function is to provide movement and flexibility in the body.

journaling A mind-body therapy in which the patient records the process of life and reflects on it to express feelings, gain new perspectives, and pay attention to what is in the unconscious.

jugular venous distention (JVD) Enlargement of the jugular vein of the neck; caused by an increase in jugular venous pressure.

justice The ethical principle that refers to patient equality.

juxtaglomerular complex Specialized cells that produce and store renin in the afferent arteriole, efferent arteriole, and distal collecting tubule; taken together, the juxtaglomerular cells and the macula densa.

K

karyotype Technique used to make an organized arrangement of all the chromosomes within one cell during the metaphase section of mitosis.

Kehr's sign Pain in the left shoulder resulting from diaphragmatic irritation; may be present in splenic injury.

keratin The protein produced by keratinocytes; makes the outermost skin layer waterproof.

keratoconjunctivitis sicca A condition of the eyes that results from changes in tear composition, lacrimal gland malfunction, or altered tear distribution; also called "dry eye syndrome."

keratoconus The degeneration of the corneal tissue resulting in abnormal corneal shape.

keratoplasty Corneal transplant. The surgical removal of diseased corneal tissue and replacement with tissue from a human donor cornea.

ketogenesis The conversion of fats to acids in the body.

ketone bodies Substances, including acetone, that are produced as by-products of the incomplete metabolism of fatty acids. When insulin is not available (as in uncontrolled diabetes mellitus), they accumulate in the blood and cause metabolic acidosis; also called "ketones."

ketorolac (Toradol) Popular nonsteroidal anti-inflammatory drug prescribed for short-term use in acute pain because it can be given orally, intramuscularly, or by IV push.

knee height caliper Device that uses the distance between the patella and heel to estimate height.

Kupffer cells Phagocytic cells that are part of the body's reticuloendothelial system and are involved in the protective function of the liver. Kupffer cells engulf harmful bacteria and anemic red blood cells.

Kussmaul respiration A type of breathing that occurs when excess acids caused by the absence of insulin increase hydrogen ion and carbon dioxide levels in the blood. This state triggers an increase in the rate and depth of

respiration in an attempt to excrete more carbon dioxide and acid.

kwashiorkor Lack of protein quantity and quality in the presence of adequate calories. Body weight is somewhat normal, and serum proteins are low.

kypophlasty A minimally invasive surgery for managing vertebral fractures in patients with osteoporosis. Bone cement is injected into the fracture site to provide pain relief, and an inflated balloon is used to restore height to the vertebra.

L

labia majora Two vertical folds of adipose tissue that extend posteriorly from the mons pubis to the perineum.

labia minora Two thinner, vertical folds of reddish epithelium that are surrounded by the labia majora.

labyrinthectomy Surgical removal of the labyrinth; used as a radical treatment of Ménière's disease when medical therapy is ineffective and the patient already has significant hearing loss.

labyrinthitis An infection of the labyrinth of the ear; may occur as a complication of acute or chronic otitis media.

laceration A type of wound characterized by tearing or mangling and usually caused by sharp objects and projectiles.

lacrimal gland A small gland that produces tears; located in the upper outer part of each ocular orbit.

lacto-ovo-vegetarian A vegetarian diet pattern in which milk, cheese, eggs, and dairy foods are eaten but meat, fish, and poultry are avoided.

lactose intolerance The inability to convert lactose (found in milk and dairy products) to glucose and galactose in the body.

lacto-vegetarian A vegetarian diet pattern in which milk, cheese, and dairy foods are eaten but meat, fish, poultry, and eggs are avoided.

lacunae Small, deep cavities within the brain that result from occlusion of a small vessel; this leads to infarct and necrosis of the area of the brain supplied by the affected vessel.

laparoscopy A minimally invasive procedure in which the surgeon makes several small incisions near the umbilicus through which a small endoscope is placed to examine the abdomen; direct examination of the pelvic cavity through an endoscope.

laparotomy An open surgical approach in which a large abdominal incision is made.

laryngitis Inflammation of the mucous membranes lining the larynx.

laryngectomy A person who has had a laryngectomy.

laryngopharynx The area behind the larynx that extends from the base of the tongue to the esophagus. It is the critical dividing point at which solid foods and fluids are separated from air.

larynx The "voice box"; it is composed of several cartilages and is located above the trachea and just below the throat at the base

of the tongue; part of the upper respiratory tract.

laser An acronym for **light amplification by stimulated emission of radiation**. As a surgical tool, a laser emits a high-powered beam of light that cuts tissue more cleanly than do scalpel blades. A laser creates intense heat, rapidly clots blood vessels or tissue, and turns target tissue (e.g., a tumor) into vapor.

laser-assisted angioplasty A procedure using heat from a laser probe that is advanced through a cannula to vaporize arteriosclerotic plaque and open the occluded or stenosed artery.

latency period The time between the initiation of a cell and the development of an overt tumor.

late-onset seizure Seizure that occurs initially more than 7 days after a head injury.

latex allergy Reactions to exposure to latex in gloves and other medical products; reactions include rashes, nasal or eye symptoms, and asthma.

latrodectism A syndrome caused by the venom of a black widow spider bite in which neurotransmitter releases from nerve terminals to cause severe abdominal pain, muscle rigidity and spasm, hypertension, and nausea and vomiting.

lead In an ECG, the provider of one view of the heart's electrical activity.

lead axis In electrocardiography, the imaginary line that joins the positive and negative poles of the lead systems.

left shift An increase in the band cells (immature neutrophils) in the white blood cell differential count; an early indication of infection.

left-sided heart (ventricular) failure Inadequacy of the left ventricle of the heart to pump adequately; results in decreased tissue perfusion from poor cardiac output and pulmonary congestion from increased pressure in the pulmonary vessels; typical causes include hypertensive, coronary artery, or valvular disease involving the mitral or aortic valve. Most heart failure begins with failure of the left ventricle and progresses to failure of both ventricles.

legally competent A person 18 years of age or older, a pregnant or a married minor, a legally emancipated (free) minor who is self-supporting, or a person not declared incompetent by a court of law.

leiomyomas Benign, slow-growing solid tumors of the uterine myometrium (muscle layer). These are the most commonly occurring pelvic tumors; also called "myomas" and "fibroids."

lens The circular, convex structure of the eye that lies behind the iris and in front of the vitreous body. Normally transparent, the lens bends the rays of light entering through the pupil so they focus on the retina. The curve of the lens changes to focus on near or distant objects.

leprosy (Hansen's disease) A chronic, contagious, systemic mycobacterial infection of the peripheral nervous system with skin involvement. The clinical course is either

progressive or self-limiting depending on the immunologic status of the host. Although the exact mechanism of infection remains unknown, studies suggest transmission via the airborne route, by insects, or through direct contact with skin lesions.

leptin A hormone that is released by fat cells and possibly by gastric cells; it also acts on the hypothalamus to control appetite.

lethargic A state of drowsiness or sleepiness.

leukemia A type of cancer with uncontrolled production of immature white blood cells in the bone marrow; the bone marrow becomes overcrowded with immature, nonfunctional cells, and the production of normal blood cells is greatly decreased.

leukocyte White blood cell (WBC); this immune system cell protects the body from the effects of invasion by organisms.

leukocytosis An elevated white blood cell count.

leukopenia A reduction in the number of white blood cells.

leukoplakia White, patchy lesions on a mucous membrane.

level I trauma center According to the American College of Surgeons, a regional resource facility that is capable of "providing leadership and total care for every aspect of injury, from prevention through rehabilitation."

level II trauma center A community facility that is capable of providing care to the vast majority of injured patients but may not be able to meet the resource needs of patients who require very complex injury management.

level III trauma center A critical link to higher-capability trauma centers in communities that do not have ready access to level I or level II centers; the primary focus is injury stabilization and patient transfer.

level IV trauma center A facility that offers advanced life support care in rural or remote settings that do not have ready access to a higher-level trauma center, such as a ski area.

LGBT Acronym for "lesbian, gay, bisexual, and transgender" culture.

libido Sexual desire.

lichenification An abnormal thickening of the skin to a leathery appearance; can occur in patients with chronic dermatitis because of their continual rubbing of the area to relieve itching.

Lichtenberg figures Branching or ferning marks that appear on the skin as a result of a lightning strike; also called "keraunographic markings" or "erythematous arborization."

life review A structured process of reflecting on one's life that is often facilitated by an interviewer.

ligament One of many bands of tissue that attach bones to other bones at joints and serve to support joints.

light reflex The reflection of the otoscope's light off the eardrum in the form of a clearly demarcated triangle of light in the normal ear.

limited scleroderma Thick skin that is limited to sites distal to the elbow and knee but also involves the face and neck.

linear fracture A type of bone fracture involving a simple, clean break in which the impacted area of bone bends inward and the area around it bends outward.

lipid Fat, including cholesterol and triglycerides, that can be measured in the blood.

lipoatrophy The loss or atrophy of subcutaneous fat; in patients with diabetes, the loss of fat tissue in areas of repeated insulin injection.

lipohypertrophy The enlargement or hypertrophy of subcutaneous fat; in patients with diabetes, an increased swelling of fat that occurs at the site of repeated insulin injections.

lipolysis The decomposition or splitting up of fat to provide fuel for energy when liver glucose is unavailable.

liposuction A cosmetic procedure to reduce the amount of adipose tissue in selected areas of the body.

lithotripsy The use of sound, laser, or dry shock wave energy to break a kidney stone into small fragments; also called “extracorporeal shock wave lithotripsy.”

living will A legal document that instructs physicians and family members about what life-sustaining treatment is wanted (or not wanted) if the patient becomes unable to make decisions.

lobectomy Surgical removal of an entire lung lobe.

lobular carcinoma in situ (LCIS) A noninvasive form of breast cancer that does not show up as a calcified cluster on a mammogram and is therefore most often diagnosed incidentally during a biopsy for another problem.

local anesthesia Anesthesia that is delivered by applying it to the skin or mucous membranes of the area to be anesthetized or by injecting it directly into the tissue around an incision, wound, or lesion.

localized pain Confined to the site of origin.

lockout interval A specific interval between doses programmed into a patient-controlled analgesia infusion pump. No drug is administered if the patient attempts to access the drug before the interval has elapsed.

locus The specific chromosome location for a gene.

log rolling Turning technique in which the patient turns all at once while his or her back is kept as straight as possible.

long-term nonprogressor (LTNP) A person who has been infected with the human immune deficiency virus for at least 10 years and has remained asymptomatic with CD4+ cell counts within a normal range. About 1% of those infected are long-term nonprogressors.

loop electrosurgical excision procedure (LEEP) Diagnostic procedure/treatment in which a thin loop-wire electrode that transmits a painless electrical current is used to cut away affected cervical cancer tissue.

lordosis The anterior concavity in the curvature of the lumbar and cervical spine when viewed from the side; a common finding in pregnancy and abdominal obesity.

Lou Gehrig's disease See *amyotrophic lateral sclerosis (ALS)*.

low back pain (LBP) Pain in the lumbosacral region of the back caused by muscle strain or spasm, ligament sprain, disk degeneration, or herniation of the nucleus pulposus from the center of the disk. Herniated disks occur most often between the fourth and fifth lumbar vertebrae (L4-5) but may occur at other levels.

lower esophageal sphincter (LES) The portion of the esophagus proximal to the gastroesophageal junction; when at rest, the sphincter is closed to prevent reflux of gastric contents into the esophagus.

lower GI series Radiographic visualization of the large intestine; usually ordered for a patient with a complaint of blood or mucus in the stool or a change in bowel pattern, such as diarrhea or constipation; also called a “barium enema.”

lower motor neurons Neurons that carry motor impulses to skeletal muscles. Patients with spinal cord injuries involving lower motor neuron lesions experience muscle wasting due to long-term flaccid paralysis.

lower urinary tract symptom (LUTS) Any of a collection of symptoms seen in benign prostatic hyperplasia, including hesitancy, intermittency, reduced force and size of the urinary stream, a sensation of incomplete bladder emptying, and postvoid dribbling.

low-intensity pulsed ultrasound A method using ultrasonic waves to promote bone union in slow-healing fractures or for new fractures as an alternative to surgery.

low-profile gastrostomy device (LPGD) A gastrostomy device that uses a firm or balloon-style internal bumper or retention disk; an antireflux valve keeps gastric contents from leaking onto the skin.

loxoscelism Systemic effects from the injected toxin of a spider bite.

lumbar puncture The insertion of a spinal needle into the subarachnoid space between the third and fourth (sometimes the fourth and fifth) lumbar vertebrae to withdraw spinal fluid for analysis; also called a “spinal tap.”

lumen The inside cavity of a tube or tubular organ, such as a blood vessel or airway.

lung compliance The quality of elasticity of the lungs.

lunula The white crescent-shaped portion of the nail at the lower end of the nail plate.

lurch An abnormality in the swing phase of gait; occurs when the muscles in the buttocks or legs are too weak to allow the person to change weight from one foot to the other.

luteal Pertaining to the post-ovulation phase of the menstrual cycle.

Lyme disease A systemic infectious disease that is caused by the spirochete *Borrelia burgdorferi* and results from the bite of an infected deer tick. Signs and symptoms include a large “bull's-eye” circular rash, malaise, fever, headache, and muscle or joint aches.

lymph Fluid that has moved out of the capillaries and is returned to the systemic circulation.

lymphadenopathy Persistently enlarged lymph nodes.

lymphedema Abnormal accumulation of protein fluid in the subcutaneous tissue of the affected limb after a mastectomy.

lymphoblastic Pertaining to abnormal leukemic cells that come from the lymphoid pathways and develop into lymphocytes.

lymphocytic Pertaining to abnormal leukemic cells that come from the lymphoid pathways.

lymphokine Cytokine produced by T-cells.

lysergic acid (LSD) The prototype major hallucinogenic drug that is odorless and colorless with a slightly bitter taste; also called “acid.”

lysis Breakage, for example, of a cell membrane.

lysozyme A component that is present in large quantities in many body secretions and dissolves the cell walls of some bacteria.

M

M phase The phase of cell division in which a single cell splits into two cells (actual mitosis).

macrocytic anemia A form of vitamin B₁₂ deficiency anemia characterized by abnormally large precursor cells.

macrovascular Referring to large blood vessels.

macular A term referring to a macula, a discolored spot on the skin that is not raised above the surface.

macular degeneration The deterioration of the macula, the area of central vision.

magnesium (Mg²⁺) A mineral that forms a cation when dissolved in water.

magnetoencephalography (MEG) A noninvasive imaging technique that measures the magnetic fields produced by electrical activity in the brain via extremely sensitive devices such as superconducting quantum interference devices (SQUIDS).

malabsorption A syndrome associated with a variety of disorders and intestinal surgical procedures and characterized by impaired intestinal absorption of nutrients.

malignant Referring to cancer.

malignant cell growth Altered cell growth that is serious and, without intervention, leads to death; cancer.

malignant hypertension A severe type of elevated blood pressure that rapidly progresses, with systolic blood pressure greater than 200 mm Hg and diastolic blood pressure greater than 150 mm Hg (greater than 130 mm Hg when there are pre-existing complications).

malignant transformation The process of changing a normal cell into a cancer cell.

malleus The outermost bony ossicle of the ear; also called the “hammer.”

malpighian layers The stratified layers of the epithelium that are formed when older keratinocytes are pushed upward.

mammography An x-ray of the soft tissue of the breast.

mandibulectomy Surgical removal of the jaw.

Manning criteria A collective term for the characteristic symptoms of irritable bowel

- syndrome: abdominal pain relieved by defecation or associated with changes in stool frequency or consistency, abdominal distention, the sensation of incomplete evacuation of stool, and the presence of mucus with stool passage.
- marasmic-kwashiorkor** A combined protein and energy malnutrition that often presents clinically when metabolic stress is imposed on a chronically starved patient.
- marasmus** A calorie malnutrition in which body fat and protein are wasted but serum proteins are often preserved.
- marsupialization** Surgical formation of a pouch that is a new duct opening.
- masklike facies** Facial expression characterized by wide-open, fixed, staring eyes caused by rigidity of the facial muscles; often seen in patients with Parkinson disease.
- mass casualty event** A situation affecting the public health that is defined based on the resource availability of a particular community or hospital facility. When the number of casualties exceeds the resource capabilities, a disaster situation is recognized to exist.
- massage** The use of various strokes and pressure to manipulate soft tissues for therapeutic purposes.
- mastication** The process of chewing.
- mastoid process** The bony ridge located over the temporal bone behind the pinna; part of the external ear.
- mastoiditis** An acute or chronic infection of the mastoid air cells caused by untreated or inadequately treated otitis media.
- matrix** In referring to bone, the substance of bone consisting chiefly of collagen, mucopolysaccharides, and lipids. Deposits of inorganic calcium salts (carbonate and phosphate) in the matrix provide the hardness of bone.
- maze procedure** An open chest surgical technique often performed with coronary artery bypass grafting for patients in atrial fibrillation with decompensation.
- McMurray test** A common diagnostic technique for the patient with a torn meniscus. The examiner flexes and rotates the knee and then presses on the medial aspect while slowly extending the leg. The test result is positive if clicking is palpated or heard; however, a negative finding does not rule out a tear.
- mean arterial pressure (MAP)** The arterial blood pressure (between 60 and 70 mm Hg) necessary to maintain perfusion of major body organs, such as the kidneys and brain.
- mechanical débridement** Method of debriding a wound by mechanical entrapment and detachment of dead tissue.
- mechanical obstruction** The physical obstruction of the bowel by disorders outside the intestine (e.g., adhesions or hernias) or by blockages in the lumen of the intestine (e.g., tumors, inflammation, strictures, or fecal impactions).
- mechanical patient lift** Electrically operated device used to lift, transfer, move, and reposition patients.
- mechanism of injury (MOI)** The manner in which a patient's traumatic event occurred, such as a high-speed motor vehicle crash or gunshot wound.
- mediastinal shift** A shift of central thoracic structures toward one side; seen on chest x-ray.
- mediastinitis** Infection of the mediastinum.
- medical command physician** As defined in a hospital's emergency response plan, the person responsible for determining the number, acuity, and medical resource needs of victims arriving from the incident scene and for organizing the emergency health care team response to injured or ill patients.
- medical harm** Physician incidents and all errors caused by members of the health care team or system that lead to patient injury or death.
- medical nutritional supplements (MNSs)** Enteral products taken by patients who cannot consume enough nutrients in their usual diet (e.g., Ensure, Boost).
- medication overuse headache** See *rebound headache*.
- meditation** A mind-body therapy using self-directed practices to relax the body and calm the mind.
- medulla** A general term for the most interior portion of an organ or structure.
- melena** Blood in the stool, with the appearance of black tarry stools.
- memory cell** A type of B-lymphocyte that remains sensitized but does not start to produce antibodies until the next exposure to the same antigen.
- menarche** A female's first menstruation, which is one sign of puberty.
- Ménière's disease** Tinnitus, one-sided sensorineural hearing loss, and vertigo that is related to overproduction or decreased reabsorption of endolymphatic fluid and causes a distortion of the entire inner canal system.
- meninges** The immediate protective covering of the brain and the spinal cord.
- meningioma** A type of benign brain tumor that arises from the coverings of the brain (the meninges) and causes compression and displacement of adjacent brain tissue.
- meningitis** Inflammation, usually bacterial or viral, of the arachnoid and pia mater of the brain and spinal cord and the cerebrospinal fluid. May be caused by bacteria or viruses; symptoms are the same regardless of the causative organism.
- meniscectomy** Surgical excision of a meniscus, as in a knee joint.
- menopause** The end of menstruation and the biologic end of reproductive ability. The term applies only to the last menstrual period. The actual date of menopause cannot be determined until at least 1 year has passed without menses.
- menses** The monthly flow of blood from the genital tract of women.
- menstruation** The cyclic shedding of the endometrial lining of the uterus.
- metabolic syndrome** A collection of related health problems with insulin resistance as a main feature. Other features include obesity, low levels of physical activity, hypertension, high blood levels of cholesterol, and elevated triglyceride levels. Metabolic syndrome increases the risk for coronary heart disease. Also called "syndrome X."
- metastasis** The growth and spread of cancer.
- metastasize** To spread cancer from the main tumor site to many other body sites.
- metastatic** Referring to disease, such as cancer, that transfers from one organ to another organ or part not directly connected; pertains to additional tumors that form after cancer cells move from the primary location by breaking off from the original group and establishing remote colonies.
- methemoglobinemia** The conversion of normal hemoglobin to methemoglobin.
- microalbuminuria** The presence of very small amounts of albumin in the urine that are not measurable by a urine dipstick or usual urinalysis procedures. Specialized assays are used to analyze a freshly voided urine specimen for microscopic levels of albumin.
- microcytic** Abnormally small in size, such as an abnormally small red blood cell.
- microvascular** Referring to small blood vessels.
- microvascular decompression** A surgical procedure to relieve the pain of trigeminal neuralgia by relocating a small artery that compresses the trigeminal nerve as it enters the pons. The surgeon carefully lifts the loop of the artery off the nerve and places a small silicone sponge between the vessel and the nerve.
- midline catheter** A type of catheter that is 6 to 8 inches long and inserted through the veins of the antecubital fossa; used in therapies lasting from 1 to 4 weeks.
- migraine headache** An episodic familial disorder manifested by a unilateral, frontotemporal, throbbing pain that is often worse behind one eye or ear. It is often accompanied by a sensitive scalp, anorexia, photophobia, and nausea with or without vomiting. Three categories of migraine headache are migraines with aura, migraines without aura, and atypical migraines.
- migratory arthritis** In the early stage of rheumatoid arthritis, symptoms that are migrating or involve more joints.
- miliary tuberculosis** See *hematogenous tuberculosis*.
- mineralocorticoids** Corticosteroids produced in the zona glomerulosa of the adrenal gland to help control the body's sodium and potassium content.
- minimally invasive direct coronary artery bypass (MIDCAB)** Surgical procedure that does not require cardiopulmonary bypass and may be used for patients with a lesion of the left anterior descending artery.
- minimally invasive esophagectomy (MIE)** A laparoscopic surgical procedure to remove part of the esophagus; may be performed in patients with early-stage cancer.

minimally invasive inguinal hernia repair (MIIHR) Surgical repair of an inguinal hernia through a laparoscope, which is the treatment of choice.

minimally invasive surgery (MIS) A general term for any surgery performed using laparoscopic technique.

miosis Constriction of the pupil of the eye.

mitochondria Within the cytoplasm of cells, the sites of production of adenosine triphosphate.

mitosis Cell division.

mitotic index The percentage of actively dividing cells within a tumor.

mitral (bicuspid) valve The atrioventricular valve that separates the left atrium of the heart from the left ventricle.

mitral regurgitation Inability of the mitral valve to close completely during systole, which allows the backflow of blood into the left atrium when the left ventricle contracts; usually due to fibrosis and calcification caused by rheumatic disease. Also called "mitral insufficiency."

mitral stenosis Thickening of the mitral valve due to fibrosis and calcification and usually caused by rheumatic fever. The valve leaflets fuse and become stiff, the chordae tendineae contract, and the valve opening narrows, preventing normal blood flow from the left atrium to the left ventricle. As a result, left atrial pressure rises, the left atrium dilates, pulmonary artery pressures increase, and the right ventricle hypertrophies.

mitral valve prolapse (MVP) Dysfunction of the mitral valve that occurs because the valvular leaflets enlarge and prolapse into the left atrium during systole; usually benign but may progress to pronounced mitral regurgitation.

mixed conductive-sensorineural hearing loss A profound hearing loss that results from a combination of both conductive and sensorineural types of hearing loss.

modifiable risk factor A factor in disease development that can be altered or controlled by the patient. Examples include elevated serum cholesterol levels, cigarette smoking, hypertension, impaired glucose tolerance, obesity, physical inactivity, and stress.

modified radical mastectomy Surgical procedure for breast cancer in which the affected breast is completely removed.

monokine Cytokine made by macrophages, neutrophils, eosinophils, and monocytes.

monosyllabic One-syllable words, such as *day*, *toe*, and *ran*, used in speech discrimination testing to determine the patient's ability to discriminate among similar sounds or among words that contain similar sounds.

mons pubis The fat pad that covers the symphysis pubis and protects it during sexual intercourse; it becomes prominent and covered with hair during puberty.

morbid obesity A weight that has a severely negative effect on health; usually more than 100% above ideal body weight or a body mass index greater than 40.

morbidity An illness or an abnormal condition or quality.

mortality Death.

Morton's neuroma Plantar digital neuritis, a condition in which a small tumor grows in a digital nerve of the foot. The patient usually describes the pain as an acute, burning sensation in the web space that involves the entire surface of the third and fourth toes.

motor Facilitating movement.

motor aphasia See *expressive aphasia*.

motor cortex Area in the frontal lobe of the brain that controls voluntary movement.

motor end plate The junction of a peripheral motor nerve and the muscle cells that it supplies.

mourning The outward social expression of loss.

mu opioids Drugs that cause side effects that include constipation, nausea and vomiting, urinary retention, pruritus (itching), sedation, and respiratory depression because of their action on the mu receptor, the most important type of opioid receptor.

mucosa The innermost layer of the gastrointestinal tract; consists of a thin layer of smooth muscle and specialized exocrine gland cells.

mucositis Open sores on mucous membranes.

multi-casualty event A disaster event in which a limited number of victims or casualties are involved and can be managed by a hospital using local resources.

multifocal Having multiple points of origin.

multigated blood pool scanning In nuclear cardiology, cardiac blood pool imaging is a noninvasive test to evaluate cardiac motion and calculate ejection fraction by using a computer to synchronize the patient's electrocardiogram with pictures obtained by a gamma-scintillation camera. In multigated blood pool scanning, the computer breaks the time between R waves into fractions of a second, called "gates." The camera records blood flow through the heart during each gate. By analyzing information from multiple gates, the computer can evaluate ventricular wall motion and calculate ejection fraction (percentage of the left ventricular volume that is ejected with each contraction) and ejection velocity.

multimodal analgesia The use of a combination of opioids, non-opioids, and local anesthetics for postoperative pain; also called "balanced analgesia."

multiple organ dysfunction syndrome (MODS) The sequence of inadequate blood flow to body tissues, which deprives cells of oxygen and leads to anaerobic metabolism with acidosis, hyperkalemia, and tissue ischemia; this is followed by dramatic changes in vital organs and leads to the release of toxic metabolites and destructive enzymes.

multiple sclerosis (MS) A chronic autoimmune disease that affects the myelin sheath and conduction pathway of the central nervous system. It is one of the leading causes of neurologic disability in persons 20 to 40 years of age.

murmur Abnormal heart sound that reflects turbulent blood flow through normal or abnormal valves; murmurs are classified according to their timing in the cardiac cycle (systolic or diastolic) and their intensity depending on their level of loudness.

Murphy's sign A sign of gallbladder disease consisting of pain that increases with deep inspiration with right subcostal palpation.

muscle biopsy The extraction of a muscle specimen for the diagnosis of atrophy (as in muscular dystrophy) and inflammation (as in polymyositis).

muscular dystrophy (MD) A group of degenerative myopathies characterized by weakness and atrophy of muscle without nervous system involvement. At least nine types have been clinically identified and can be broadly categorized as slowly progressive or rapidly progressive.

mutation A change in deoxyribonucleic acid (DNA) that is passed from one generation to another.

myalgia Muscle aches/muscle pain.

myasthenia gravis (MG) A chronic autoimmune disease of the neuromuscular junction. It is characterized by remissions and exacerbations, with fatigue and weakness primarily in the muscles innervated by the cranial nerves and in the skeletal and respiratory muscles. It ranges from mild disturbances of the ocular muscles to a rapidly developing, generalized weakness that may lead to death from respiratory failure.

myasthenic crisis Undermedication with cholinesterase inhibitors.

mydriasis Dilation of the pupil of the eye.

myelin sheath A white, lipid covering of the axon.

myelocytic Pertaining to leukemias in which the abnormal cells come from the myeloid pathways.

myelogenous Pertaining to leukemias in which the abnormal cells come from the myeloid pathways.

myelography Radiography of the spine after injection of contrast medium into the subarachnoid space of the spine; used to visualize the vertebral column, intervertebral disks, spinal nerve roots, and blood vessels.

myelosuppression Suppression of bone marrow activity that causes decreased numbers of blood cells (pancytopenia).

myocardial contractility The force of cardiac contraction independent of preload.

myocardial hypertrophy Enlargement of the myocardium.

myocardial infarction (MI) Injury and necrosis of myocardial tissue that occurs when the tissue is abruptly and severely deprived of oxygen; usually caused by atherosclerosis of a coronary artery, rupture of the plaque, subsequent thrombosis, and occlusion of blood flow.

myocardial nuclear perfusion imaging (MNPI) The use of radionuclide techniques in which radioactive tracer substances are used to view, record, and evaluate cardiovascular abnormalities; useful for detecting myocardial

infarction and decreased myocardial blood flow and for evaluating left ventricular ejection.

myocardium The heart muscle.

myoclonic seizure A type of generalized seizure characterized by a brief jerking or stiffening of the extremities. The contractions last for just a few seconds and may be symmetric or asymmetric.

myofibril sarcomere The basic contractile unit of the myocardial cell.

myoglobin A low-molecular-weight heme protein found in cardiac and skeletal muscle; an early marker of myocardial infarction.

myoglobinuria The release of muscle myoglobin into the urine.

myoglobinuric renal failure Renal failure that is caused by the release of myoglobin (muscle protein) from injured muscle tissues into the circulation. Myoglobin, which is believed to have a direct toxic effect on the kidney, can occlude the distal convoluted tubule and precipitate acute renal failure.

myomectomy The surgical removal of leiomyomas with preservation of the uterus.

myometrium The thick, middle, muscular layer of the body of the uterus. Contraction of these muscle fibers can expel the products of conception and can constrict the blood vessels to control bleeding after childbirth.

myopathy A problem in muscle tissue.

myopia An error of refraction that occurs when the eye over-refracts or over-bends the light and focuses images in front of the retina; this results in normal near vision but poor distance vision; also called "nearsightedness."

myositis Inflammation of a muscle.

myosplint Electrical stimulation of tension splints in the heart to help the ventricle change to a more normal shape in the patient with heart failure; under investigation in Europe and the United States.

myringoplasty Surgical reconstruction of the eardrum.

myringotomy The surgical creation of a hole in the eardrum; performed to drain middle-ear fluids and relieve pain in the patient with otitis media (middle-ear infection).

myxedema Dry, waxy swelling of the skin that is accompanied by nonpitting edema (especially around the eyes, in the hands and feet, and between the shoulder blades) and is associated with primary hypothyroidism.

myxedema coma A rare, serious complication of untreated or poorly treated hypothyroidism in which decreased metabolism causes the heart muscle to become flabby and the chamber size to increase, resulting in decreased cardiac output and decreased perfusion to the brain and other vital organs.

N

nadir In chemotherapy, the period of greatest bone marrow suppression, when the patient's platelet count may be very low.

nasoduodenal tube (NDT) A tube that is inserted through a nostril and into the small intestine.

nasoenteric tube (NET) Any feeding tube that is inserted nasally and then advanced into the gastrointestinal tract.

nasogastric (NG) tube A tube that is inserted through a nostril and into the stomach for liquid feeding or for withdrawing gastric contents.

nasotracheal The route for inserting a tube into the trachea via the nose.

National Patient Safety Goals Goals published by The Joint Commission that require health care organizations to focus on specific priority safety practices.

natural chemical débridement Method of debriding a wound by creating an environment that promotes self-digestion of dead tissues by bacterial enzymes.

naturopath Holistic care provider who uses a combination of physical therapies, herbal preparations, homeopathic remedies, acupuncture, and lifestyle changes to improve health.

naturopathic medicine The practice of medicine that incorporates herbs and nutrition into its health care practice.

near point of vision The closest distance at which the eye can see an object clearly.

near-drowning Recovery after submersion in a liquid medium (usually water); this term is no longer used because language that describes drowning incidents has been standardized.

near-euglycemic A term that refers to near-normal blood glucose levels.

near-syncope Dizziness with an inability to remain in an upright position.

necrosis Cell death, or infarction.

necrotic arachnidism A necrotic wound resulting from a spider bite.

necrotizing hemorrhagic pancreatitis (NHP) Inflammation of the pancreas that is characterized by diffusely bleeding pancreatic tissue with fibrosis and tissue death. This form affects about 20% of patients with pancreatitis.

necrotizing vasculitis A group of diseases whose primary manifestation is inflammation of arterial walls, which causes ischemia in the tissues usually supplied by the involved vessels.

needle thoracostomy A quick, temporary method of chest decompression in which a large-bore needle is used to vent trapped air pending chest tube insertion.

negative deflection In electrocardiography, the flow of electrical current in the heart (cardiac axis) away from the positive pole and toward the negative pole.

negative feedback control mechanism The condition of maintaining a constant output of a system by exerting an inhibitory control on a key step by a product of that system. Used in a series of reactions that control hormone secretion and cellular activity based on responses to correct any movement away from normal function. An example of a simple negative feedback hormone response is the control of insulin secretion in which the action of insulin (decreasing blood glucose levels) is the opposite of the condition that stimulated insulin secretion (elevated blood glucose levels).

negative nitrogen balance A net loss of protein that occurs when the breakdown (degradation) of protein exceeds buildup (synthesis).

neglect In nursing, failure to provide for a patient's basic needs.

neoadjuvant therapy Treatment of a cancerous tumor with chemotherapy to shrink the tumor before it is surgically removed.

neoplasia Any new or continued cell growth not needed for normal development or replacement of dead and damaged tissues.

nephrectomy The surgical removal of the kidney.

nephrolithiasis The formation of stones in the kidney.

nephron The "working" unit of the kidney where urine is formed from blood. Each kidney consists of about 1 million nephrons, and each nephron separately makes urine. There are two types of nephrons: cortical and juxtamedullary.

nephropathy Pathologic change in the kidney that reduces kidney function and leads to renal failure.

nephrosclerosis Thickening in the nephron blood vessels that results in narrowing of the vessel lumen, with decreased renal blood flow and chronically hypoxic kidney tissue.

nephrostomy The surgical creation of an opening directly into the kidney; performed to divert urine externally and prevent further damage to the kidney when a stricture is causing hydronephrosis and cannot be corrected with urologic procedures.

nephrotic syndrome (NS) A condition of increased glomerular permeability that allows larger molecules to pass through the membrane into the urine and be removed from the blood. This process causes massive loss of protein into the urine, edema formation, and decreased plasma albumin levels.

nephrotoxicity (nephrotoxic) The disruption of kidney function.

neuritic plaques Degenerating nerve terminals found particularly in the hippocampus, an important part of the limbic system, and marked by increased amounts of an abnormal protein called "beta amyloid"; a characteristic change of the brain found in patients with Alzheimer's disease.

neuroaxial Referring to the epidural or spinal area.

neuroendocrine regulation The regulation of overall body function by the combined actions of the endocrine system and the nervous system.

neurofibrillary tangles Tangled masses of fibrous elements throughout the neurons; a classic finding at autopsy in the brains of patients with Alzheimer's disease.

neurogenic shock Hypotension and bradycardia associated with cervical spinal injuries and caused by a loss of autonomic function. The patient is at greatest risk in the first 24 hours after injury.

neuroglial cells Cells of varying size and shape that provide protection, structure, and nutrition for the neurons.

neurohypophysis The posterior lobe of the pituitary gland that stores hormones produced in the hypothalamus.

neurolysis Permanent nerve destruction.

neuroma A sensitive tumor consisting of nerve cells and nerve fibers.

neuropathic pain A type of chronic noncancer pain that results from a nerve injury. Examples of causes include diabetic neuropathy, postherpetic neuralgia, radiculopathy (spinal nerve damage), and trigeminal neuralgia. Neuropathic pain is described as burning, shooting, stabbing, and the sensation of “pins and needles.”

neuropathy A progressive deterioration of nerves that results in loss of nerve function. A common complication of diabetes, it often involves all parts of the body.

neurotransmitter Regulatory chemical that exerts inhibitory (slowing down) or excitatory (speeding up) activity at postsynaptic nerve cell membranes. Acetylcholine, norepinephrine, epinephrine, dopamine, and serotonin are neurotransmitters.

neurovascular assessment Assessment of the neuromuscular system that includes inspection of skin color, temperature, and capillary refill distal to an injury, surgical procedure, or cast. Palpation of pulses in the extremities below level of injury and assessment of sensation, movement, and pain in the injured part give a complete assessment.

neutralization See *inactivation*.

neutropenia Decreased numbers of leukocytes, especially neutrophils, which causes immunosuppression.

neutrophilia Increased number of circulating neutrophils.

nevus A mole; a benign skin growth of the pigment-forming cells.

new-onset angina Cardiac chest pain that occurs for the first time.

nitroglycerin (NTG) A drug prescribed for patients with angina. It increases collateral blood flow, redistributes blood flow toward the subendocardium, and causes dilation of the coronary arteries.

nits Lice eggs.

NMDA (*N*-methyl-D-aspartate) receptor antagonist A group of drugs that block excess amounts of glutamate, which damages nerve cells in the brain; used to treat Alzheimer's disease.

nociceptive pain Pain related to the skin, musculoskeletal structures, or body organs.

nocturia The need to urinate excessively at night. Also called “nocturnal polyuria.”

nocturnal polyuria See *nocturia*.

nodule A small node. In the vocal cords, enlarged fibrous tissue caused by infectious processes or overuse of the voice.

nonabsorbable suture Suture that becomes encapsulated in the tissue during the healing process and remains in the tissue unless removed; made of silk, cotton, steel, nylon, polyester, or other synthetic material.

nonadherence In health care, accidental failure by a patient to take medication.

noncompliance In health care, deliberate failure by a patient to take medication.

non-exertional heat stroke See *classic heat stroke*.

noninvasive temporary pacing (NTP) Cardiac pacing that is accomplished through the application of two large external electrodes attached to an external pulse generator; used as an emergency measure to provide demand ventricular pacing in a profoundly bradycardic or asystolic patient until invasive pacing can be instituted or the patient's intrinsic rate returns to normal.

nonmechanical obstruction Intestinal obstruction that does not involve a physical obstruction in or outside the intestine. Instead, decreased or absent peristalsis results in a slowing of the movement or a backup of intestinal contents. This is also known as “paralytic ileus” or “adynamic ileus” because it is a result of neuromuscular disturbance.

nonmodifiable risk factor Factor in disease development that cannot be altered or controlled by the patient. Examples include age, gender, family history, and ethnic background.

nonprogressive (compensatory) stage of shock The stage of shock that occurs when kidney and hormonal mechanisms are activated because cardiovascular compensation alone is not enough to maintain mean arterial pressure and supply needed oxygen to the vital organs.

nonsteroidal anti-inflammatory drugs (NSAIDs) Potent anti-inflammatory agents that inhibit the synthesis of prostaglandins, thus decreasing pain and inflammation.

nonsustained ventricular tachycardia (NSVT) Occurrence of three or more successive premature ventricular complexes.

non tunneled percutaneous central catheter A type of catheter, usually 15 to 20 cm long and with dual or triple lumens, that is inserted through the subclavian vein in the upper chest or through the jugular veins in the neck using sterile technique.

nonurgent In a three-tiered triage scheme, the category that includes patients who can generally tolerate waiting several hours for health care services without a significant risk of clinical deterioration, such as those with sprains, strains, or simple fractures.

“normal” adult blood pressure According to 2003 guidelines, blood pressure less than 120 mm Hg systolic and less than 80 mm Hg diastolic in adults.

normal flora The microorganisms living in or on the human host without causing disease; the bacteria that are characteristic of each body location. Normal flora often compete with and prevent infection from unfamiliar microorganisms attempting to invade a body site.

normal sinus rhythm (NSR) The rhythm originating from the sinoatrial node (dominant pacemaker), with atrial and ventricular rates of 60 to 100 beats/min and regular atrial and ventricular rhythms.

normotonic See *isosmotic*.

North American pit vipers The Crotalidae, one of two families of indigenous poisonous snakes in North America; named for the characteristic depression between each eye and nostril. They include rattlesnakes, copperheads, and water moccasins and account for most poisonous snakebites in the United States.

nosocomial infection Acquired in an inpatient health care setting; for example, infections that were not present at hospital admission; also called “hospital-acquired infections” and “health care-associated infections.”

nothing by mouth (NPO) No eating, drinking (including water), or smoking.

nuchal rigidity Stiff neck, which can be a sign of cerebrospinal fluid leak; nuchal rigidity is not checked until a spinal cord injury has been ruled out.

nucleoside What the four bases in deoxyribonucleic acid (DNA) (adenine, guanine, cytosine, thymine) become when a five-sided sugar (deoxyribose sugar) attaches to them.

nucleotide The final form of a base that actually gets put into the strand of deoxyribonucleic acid. A nucleoside becomes a complete nucleotide by the attachment of phosphate groups.

nulliparity The condition of never having given birth.

nurse technician See *nursing assistant*.

nursing assistant A member of the rehabilitative health care team who assists the registered nurse in the care of patients.

nutritional screening A screening by the health care provider that includes visual inspection, measured height and weight, weight history, usual eating habits, ability to chew and swallow, and any recent changes in appetite or food intake. The screening is a way to determine which patients need more extensive nutritional assessment.

nutritional status Reflects the balance between nutrient requirements and intake.

nutritionist A member of the health care team who ensures patients meet their nutritional needs. Also called “dietitian.”

nystagmus Involuntary, rapid eye movements.

O

obesity An increase in body weight at least 20% above the upper limit of the normal range for ideal body weight, with an excess amount of body fat; in an adult, a body mass index greater than 30.

obligatory urine output The minimum amount of urine per day needed to dissolve and excrete toxic waste products.

obstipation The inability to pass stool; intractable constipation.

obstruction Blockage.

obstructive jaundice Jaundice caused by an impediment to the flow of bile from the liver to the duodenum; may be caused by edema of the ducts or gallstones.

- occlusion** Blockage.
- occlusive stroke** A type of brain attack caused by ischemia (interruption in blood flow) in the brain tissue supplied by the affected artery.
- Occupational Safety and Health Administration (OSHA)** A federal agency that protects workers from injury or illness at their place of employment.
- occupational therapist (OT, OTR)** A member of the rehabilitation health care team who works to develop the patient's fine motor skills used for activities of daily living and the skills related to coordination and cognitive retraining.
- odynophagia** Pain on swallowing.
- oligomenorrhea** Scant or infrequent menses.
- oligospermia** Low sperm count.
- oliguria** Decreased excretion of urine in relation to amount of fluid intake; usually defined as urine output less than 400 mL/day.
- omentectomy** Surgical removal of the connective tissues covering the pelvic organs.
- oncogene** Proto-oncogene that has been "turned on" and can cause cells to change from normal cells to cancer cells.
- oncogenesis** Cancer development.
- oncogenic osteomalacia** Osteomalacia that is caused by malignant tumors of the bone; also called "tumor-induced osteomalacia."
- oncovirus** Virus that causes cancer.
- oophorectomy** Surgical removal of the ovary.
- open fracture** A fracture in which the skin surface over the broken bone is disrupted, causing an external wound; also called "compound fracture."
- open head injury** A type of traumatic primary brain injury that occurs with a skull fracture or when the skull is pierced by a penetrating object. The integrity of the brain and the dura is violated and there is exposure to outside contaminants, with damage to the underlying vessels, dural sinus, brain, and cranial nerves.
- open reduction** The reduction of a fracture after surgical incision into the site to allow direct visualization of the fracture. See *internal fixation*.
- ophthalmoplegia** Paralysis or weakness of the eye muscles.
- opioids** Any of a group of drugs made from the Asian poppy or produced as a synthetic drug that produces the same effects of the opium plant. The street term for opioids is "narcotics" or "narcs."
- opportunistic infection** Infection caused by organisms that are present as part of the normal environment and would be kept in check by normal immune function.
- optic disc** The point at the inside back of the eye where the optic nerve enters the eyeball. It appears as a creamy pink to white depressed area in the retina and contains only nerve fibers and no photoreceptor cells.
- optic fundus** The area at the inside back of the eye that can be seen with an ophthalmoscope.
- optic nerve** The nerve of sight; connects the optic disc to the brain.
- orbit** The bony socket of the skull that surrounds and protects the eye along with the attached muscles, nerves, vessels, and tear-producing glands.
- orchiectomy** The surgical removal of one or both testes.
- orchitis** An acute testicular inflammation resulting from trauma or infection.
- orexin** Neuropeptide that is an appetite stimulant.
- organ of Corti** The receptor end-organ of hearing located on the basilar membrane of the cochlea; contains hair cells that detect vibration from sound and stimulate the eighth cranial nerve.
- orotracheal** The route for inserting a tube into the trachea via the mouth.
- orthopnea** Shortness of breath that occurs when lying down but is relieved by sitting up.
- orthostatic** Pertaining to or caused by standing erect.
- orthostatic hypotension** A decrease in blood pressure (20 mm Hg systolic and/or 10 mm Hg diastolic) that occurs during the first few seconds to minutes after changing from a sitting or lying position to a standing position; also called "postural hypotension."
- orthotopic transplantation** The most common type of transplantation procedure in which a diseased organ is removed and a donor organ is grafted in its place. For example, during heart transplantation, the surgeon removes the diseased heart and leaves the posterior walls of the patient's atria, which serve as the anchor for the donor heart; anastomoses are made between the recipient and donor atria, aorta, and pulmonary arteries.
- osmolality** The number of milliosmoles in a kilogram of solution.
- osmolarity** The number of milliosmoles in a liter of solution.
- osmosis** The movement of a solvent across a semipermeable membrane (a membrane that allows the solvent, but not the solute, to pass through) from a lesser to a greater concentration.
- osteitis deformans** A metabolic disorder of bone remodeling, or turnover, in which increased resorption or loss results in bone deposits that are weak, enlarged, and disorganized; also called "Paget's disease."
- osteoarthritis** Noninflammatory form of arthritis characterized by the progressive deterioration and loss of cartilage in one or more joints; most common form of arthritis.
- osteoblast** Cell associated with formation of bone.
- osteoblastic** Referring to bone production activity.
- osteoclast** Cell associated with destruction or resorption of bone.
- osteoclastic** Referring to bone destruction.
- osteocyte** Bone cell.
- osteogenic** Originating from bone.
- osteomalacia** Abnormal softening of the bone tissue characterized by inadequate mineralization of osteoid. It is the adult equivalent of rickets (vitamin D deficiency) in children.
- osteomyelitis** An inflammation of bone tissue caused by pathogenic microorganisms; produces an increased vascularity and edema often involving the surrounding soft tissues.
- osteonecrosis** See *avascular necrosis*.
- osteopenia** A condition of low bone mass that occurs when there is a disruption in the bone remodeling process.
- osteophyte** Bone spur.
- osteoporosis** A metabolic disease in which bone demineralization results in decreased density and subsequent fractures.
- osteotomy** Surgical resection of bone.
- ostomate** A patient with an ostomy.
- ostomy** The surgical creation of an opening, usually referring to an opening in the abdominal wall; stoma.
- otorrhea** Ear discharge.
- otosclerosis** Irregular bone growth around the ossicles.
- otoscope** An instrument used to examine the ear; consists of a light, a handle, a magnifying lens, and a pneumatic bulb for injecting air into the external canal to test mobility of the eardrum.
- ototoxic** Having a toxic effect on the inner ear structures.
- ototoxicity** Disruption of hearing and/or balance.
- outflow disease** Chronic peripheral arterial disease with obstruction at or below the superficial femoral or popliteal artery. The patient experiences burning or cramping in the calves, ankles, feet, and toes after walking a certain distance; the pain usually subsides with rest.
- outpatient** A patient who goes to the hospital for treatment and returns home on the same day.
- ovaries** A pair of almond-shaped organs that are located near the lateral walls of the upper pelvic cavity. They develop and release ova and produce the sex steroid hormones (estrogen, progesterone, androgen, and relaxin).
- overflow (urinary) incontinence** The involuntary loss of urine when the bladder is overdistended.
- overhydration** See *fluid overload*.
- overweight** An increase in body weight for height compared with a reference standard (e.g., the Metropolitan Life height and weight tables) or 10% greater than ideal body weight. However, this weight may not reflect excess body fat, which in an adult is a body mass index of 25 to 30.
- ovoid pupil** In evaluating pupils for size and reaction to light, the midstage between a normal-size pupil and a dilated pupil; indicates the development of increased intracranial pressure.
- ovulation** The cyclic maturation of a dominant follicle (the graafian follicle) in the ovary and the subsequent release of the ovum.
- oxygen concentrator** A machine that removes nitrogen, water vapor, and hydrocarbons from room air.
- oxygen dissociation** The transfer of oxygen from hemoglobin to tissues.

P

P wave In the electrocardiogram, the deflection representing atrial depolarization.

pacemaker In the cardiac conduction system, the sinus node.

pack-years The number of packs of cigarettes per day multiplied by the number of years the patient has smoked; used in recording the patient's smoking history.

Paget's disease An alternative name for "osteitis deformans," a metabolic disorder of bone remodeling, or turnover, in which increased resorption or loss results in bone deposits that are weak, enlarged, and disorganized.

pain An unpleasant sensory and emotional experience associated with actual or potential tissue damage; the most reliable indication of pain is the patient's self-report.

palliation Relieving symptoms.

palliative care A compassionate and supportive approach to patients and families who are living with life-threatening illnesses; involves a holistic approach that provides relief of symptoms experienced by the dying patient.

palliative sedation A care management approach involving the administration of drugs such as benzodiazepines for the purpose of lowering of patient consciousness.

palliative surgery Surgery done to make the patient more comfortable.

palpitations A feeling of fluttering in the chest, an unpleasant awareness of the heartbeat, and an irregular heartbeat; may result from a change in heart rate or rhythm or from an increase in the force of heart contractions.

pancreatic abscess A collection of purulent material that results from extensive inflammatory necrosis of the pancreas after infection by organisms such as *Escherichia coli*; the most serious complication of pancreatitis. It is fatal if left untreated.

pancreatic pseudocyst A false cyst, so named because, unlike a true cyst, it does not have an epithelial lining. It is an encapsulated saclike structure that forms on or surrounds the pancreas and develops as a complication of acute or chronic pancreatitis. It may contain up to several liters of straw-colored or dark-brown viscous fluid, the enzymatic exudate of the pancreas.

pancreaticojejunostomy Surgical anastomosis of the pancreatic duct with the jejunum.

pancytopenia A deficiency of all three cell types (red blood cells, white blood cells, and platelets) of the blood.

pandemic A general epidemic spread over a wide geographic area and affecting a large proportion of the population.

panhypopituitarism The decreased production of all anterior pituitary hormones; an extremely rare condition.

panniculectomy The surgical removal of any panniculus, most often the abdominal apron; usually done as a follow-up to bariatric surgery in an obese patient.

panniculitis Infection of the panniculus.

panniculus A layer of membrane; also used to refer to skinfold areas in the obese patient.

pannus Vascular granulation tissue composed of inflammatory cells that forms in a joint space; erodes articular cartilage and eventually destroys bone.

Papanicolaou test (Pap smear) A cytologic study that is effective in detecting precancerous and cancerous cells obtained from the cervix.

papilla The anatomic term for a small, nipple-shaped projection or structure.

papilledema Edema and hyperemia of the optic disc; a sign of increased intracranial pressure found on ophthalmoscopic examination; also called a "choked disc."

papilloma A pedunculated outgrowth of tissue.

papillotomy An incision of a papilla, a small nipple-shaped projection or structure.

papular Referring to a papule, a small, solid elevation of the skin.

paracentesis A procedure in which the physician inserts a trocar catheter into the abdomen to remove and drain ascitic fluid from the peritoneal cavity.

paradoxical blood pressure (paradoxical pulse) An exaggerated decrease in systolic pressure by more than 10 mm Hg during the inspiratory phase of the respiratory cycle (normal is 3 to 10 mm Hg); clinical conditions that may produce a paradoxical blood pressure include pericardial tamponade, constrictive pericarditis, and pulmonary hypertension.

paradoxical chest movement The "sucking inward" of the loose chest area during inspiration and a "puffing out" of the same area during expiration in a patient with a flail chest.

paradoxical splitting Abnormal splitting of the S₂ heart sound heard in patients with severe myocardial depression; causes early closure of the pulmonic valve or a delay in aortic valve closure.

paralysis Absence of movement.

paralytic ileus Absence of peristalsis.

paramedic Prehospital care provider for patients who require care that exceeds basic life support resources. Advanced life support (ALS) may include cardiac monitoring, advanced airway management and intubation, establishing IV access, and administering drugs en route to the emergency department.

paranasal sinuses The air-filled cavities within the bones that surround the nasal passages. Lined with ciliated membrane, the sinuses provide resonance during speech and decrease the weight of the skull.

paraparesis Weakness that involves only the lower extremities, as seen in lower thoracic and lumbosacral injuries or lesions.

paraplegia Paralysis that involves only the lower extremities, as seen in lower thoracic and lumbosacral injuries or lesions.

parathyroid hormone (PTH) A hormone released from the parathyroid glands in response to decreased serum calcium levels.

parenchyma A general term for the functional elements of an organ as differentiated from its framework (stroma).

paresis Weakness.

paresthesia Abnormal or unusual nerve sensations of touch, such as tingling and burning.

parietal cells Cells lining the wall of the stomach that secrete hydrochloric acid and produce intrinsic factor.

Parkinson disease (PD) A debilitating neurologic disease that affects motor ability and is characterized by four cardinal symptoms: tremor, rigidity, akinesia (slow movement), and postural instability. It is the third most common neurologic disorder of older adults; also called "paralysis agitans."

parotidectomy The surgical removal of the parotid glands.

paroxysmal nocturnal dyspnea (PND) In the patient with heart disease, difficulty breathing that develops after lying down for several hours and causes the patient to awaken abruptly with a feeling of suffocation and panic. Occurs because the heart is unable to compensate for the increased volume when blood from the lower extremities is redistributed to the venous system, which increases venous return to the heart. A diseased heart is ineffective in pumping the additional fluid into the circulatory system, and pulmonary congestion results.

paroxysmal supraventricular tachycardia (PSVT) A form of supraventricular tachycardia that occurs when the rhythm is intermittent, initiated suddenly by a premature complex such as a premature atrial complex, and terminated suddenly with or without intervention.

partial seizure One of the three broad categories of seizure disorders along with generalized seizure and unclassified seizure. Partial seizures are of two types: complex and simple. Partial seizures begin in a part of one cerebral hemisphere; some can evolve into generalized tonic-clonic, tonic, or clonic seizures. They are most often seen in adults and in general are less responsive to medical treatment; also called "focal seizures" or "local seizures."

passive euthanasia See *withdrawing or withholding life-sustaining therapy*.

passive immunity Resistance to infection that is of short duration (days or months) and either natural by transplacental transfer from the mother or artificial by injection of antibodies (e.g., immunoglobulin).

passive smoking The exposure to second-hand smoke produced by a person smoking cigarettes.

pathogen Any microorganism capable of producing disease.

pathogenicity The ability to cause disease.

pathologic (spontaneous) fracture A fracture that occurs after minimal trauma to a bone that has been weakened by a disease such as bone cancer or osteoporosis.

patient-centered care Care that recognizes the patient or designee as the source of control

and full partner in providing compassionate and coordinated care based on respect for the patient's preferences, values, and needs.

patient-controlled analgesia A method that allows the patient to control the dosage of opioid analgesia received by using an infusion pump to deliver the desired amount of medication through a conventional IV route.

patients Recipients of care in mutually trusting relationships with nurses and other members of the health care team.

PDSA Acronym for **plan, do, study, analysis**.

peak expiratory flow (PEF) The fastest airflow rate reached at any time during exhalation.

peau d'orange A dimpled appearance of the skin, resembling an orange peel.

pedal Pertaining to the feet.

pediculosis An infestation by human lice.

pedigree A graph of a family history for a specific trait or health problem over several generations.

pelvic inflammatory disease (PID) Any infection of the pelvis involving the upper genital tract beyond the cervix in women. It occurs when organisms from the lower genital tract migrate from the endocervix upward through the uterine cavity into the fallopian tubes.

pemphigus vulgaris A rare, chronic blistering disease that can occur anywhere on the skin and is associated with high morbidity and mortality rates. It is caused by an autoimmune disorder that occurs most often during middle and old age.

penectomy Surgical removal of the penis.

penetrance In genetics, how often or how well a gene is expressed when it is present within a population.

penetrating injury See *penetrating trauma*.

penetrating trauma Injuries caused by piercing; classified by the velocity of the vehicle (e.g., knife or bullet) causing the injury. Low-velocity injuries from knife wounds cause damage directly at the site; high-velocity injuries from gunshot wounds cause both direct and indirect damage; also called "penetrating injury."

penis An organ for urination and intercourse. It consists of the body or shaft and the glans penis (the distal end of the penis).

peptic ulcer A mucosal lesion of the stomach or duodenum.

peptic ulcer disease (PUD) The impairment of gastric mucosal defenses so they no longer protect the epithelium from the effects of acid and pepsin.

percussion notes The sounds heard upon striking a part of the body with short, sharp blows; aids diagnosis through a systematic assessment of changes in the sound quality obtained.

percutaneous Performed through the skin.

percutaneous alcohol septal ablation Surgical procedure for hypertrophic cardiomyopathy (HCM) in which alcohol is injected into a target septal branch of the left anterior descending coronary artery to produce a small

septal infarction. This procedure also widens the left ventricular outflow tract.

percutaneous electrical nerve stimulation (PENS) See *transcutaneous electrical nerve stimulation (TENS)*.

percutaneous endoscopic gastrostomy (PEG) A stoma created from the abdominal wall into the stomach for insertion of a short feeding tube.

percutaneous stereotactic rhizotomy (PSR) Procedure performed under general anesthesia to treat trigeminal neuralgia; a hollow needle is passed through the inside of the patient's cheek into the trigeminal nerve fibers, and a heating current (radiofrequency thermocoagulation) goes through the needle to destroy some of the fibers.

percutaneous transhepatic cholangiography (PTC) The radiographic study of the biliary duct system using an iodinated dye instilled via a percutaneous needle inserted through the liver into the intrahepatic ducts. It may be performed when a patient has jaundice or persistent upper abdominal pain, even after cholecystectomy, but it is rarely performed as a diagnostic procedure.

percutaneous transluminal angioplasty (PTA) A nonsurgical method of improving arterial flow by opening the vessel lumen and creating a smooth inner vessel surface. One or more arteries are dilated with a balloon catheter advanced through a cannula, which is inserted into or above an occluded or stenosed artery.

percutaneously Performed through the skin and other tissues.

perforate To break open or pierce through a part.

pericardial effusion Complication of pericarditis that occurs when the space between the parietal and visceral layers of the pericardium fills with fluid.

pericardial friction rub An abnormal sound that originates from the pericardial sac and occurs with the movements of the heart during the cardiac cycle; usually transient and a sign of inflammation, infection, or infiltration; may be heard in patients with pericarditis resulting from myocardial infarction, cardiac tamponade, or post-thoracotomy.

pericardiectomy Surgical excision of the pericardium (the sac around the heart).

pericardiocentesis Withdrawal of pericardial fluid through a catheter inserted into the pericardial space to relieve the pressure on the heart.

perichondrium A tough, fibrous tissue layer that surrounds the ear cartilage and gives shape to the pinna.

perimenopause Menopause transition; changes in spontaneous ovarian function that precede the last menstrual period and occur gradually. Common features are a change in the woman's usual menstrual periods and the beginning of vasomotor symptoms, such as hot flushes and night sweats.

perineum The area between the vaginal opening and the anus. The skin of the

perineum covers the muscles, fascia, and ligaments that support the pelvic structures.

periodontal disease Gum disease in which mandibular bone loss has occurred.

perioperative The operative experience consisting of the preoperative, intraoperative, and postoperative time periods.

peripheral blood stem cells (PBSCs) Stem cells that are collected from peripheral blood for transplantation into the patient.

peripheral chemoreceptors Several 1- to 2-mm collections of tissue identified in the carotid arteries and along the aortic arch.

peripheral IV therapy IV therapy in which a vascular access device (VAD) is placed in a peripheral vein, usually in the arm.

peripheral neuropathy (PN) A general term for inflammation of peripheral nerves; also called "polyneuritis" and "polyneuropathy."

peripheral vascular disease (PVD) Any disorder that alters the natural flow of blood through the arteries and veins of the peripheral circulation.

peripherally inserted central catheter (PICC) A long catheter inserted through a vein of the antecubital fossa (inner aspect of the bend of the arm) or the middle of the upper arm.

peritonitis Acute inflammation of the visceral/parietal peritoneum and endothelial lining of the abdominal cavity, or peritoneum.

peritonsillar abscess (PTA) A complication of acute tonsillitis. The infection spreads from the tonsil to the surrounding tissue, which forms an abscess.

periungual lesion Skin lesion around the nail bed.

permeable The quality of being porous.

pernicious anemia A form of megaloblastic anemia caused by failure to absorb vitamin B₁₂ because of a deficiency of intrinsic factor (normally secreted by the gastric mucosa) needed for intestinal absorption of vitamin B₁₂.

PERRLA An acronym that stands for the phrase "Pupils should be equal in size, round and regular in shape, and react to light and accommodation."

persistent pain See *chronic pain*.

personal emergency preparedness plan An individual plan that outlines specific arrangements in the event of disaster, such as child-care, pet care, and older adult care.

personal protective equipment (PPE) Infection control protocol that refers to the use of gloves, isolation gowns, face protection, and respirators with N95 or higher filtration.

personal readiness supplies A preassembled disaster supply kit for the home and/or automobile that contains clothing and basic survival supplies; also called a "go bag."

petechiae Pinpoint red spots on the mucous membranes, palate, conjunctivae, or skin.

pH A measure of the free hydrogen ion level in body fluid.

phagocytosis The process of engulfing, ingesting, killing, and disposing of an invading

organism by neutrophils and macrophages; a key process of inflammation.

Phalen's maneuver (or Phalen's wrist test) Test to determine the presence of carpal tunnel syndrome (CTS); a positive test for CTS cause paresthesia in the medial nerve distribution of the palm of the hand in 60 seconds.

phantom limb pain (PLP) A frequent complication of amputation in which the patient perceives sensation in the absent (amputated) foot or hand. This sensation usually diminishes over time.

pharmacologic stress echocardiogram A form of echocardiography in which either dobutamine (increases heart's contractility) or adenosine (dilates coronary arteries) is given to the patient; usually used when patients cannot tolerate exercise.

pharynx The throat, which extends from the soft palate to the esophagus and is lined with mucous membrane; part of the upper respiratory tract.

phenotype Any genetic characteristic that can actually be observed or, in some cases, determined by laboratory test.

pheochromocytoma A tumor of the adrenal medulla, which can cause excessive secretion of catecholamines.

pheresis A procedure in which whole blood is withdrawn from the patient, a blood component (such as stem cells) is filtered out, and the plasma is returned to the patient.

phimosis A tight foreskin of the penis, which cannot be retracted.

phlebitis Inflammation of a vein, which can predispose patients to thrombosis.

phlebothrombosis Presence of a thrombus in a vein without inflammation.

phlebotomy Drawing of blood from a vein.

phonation Normal speech.

phonophobia Abnormal sensitivity to sound.

phonophoresis Treatment for back pain in which a topical drug (e.g., lidocaine, hydrocortisone) is applied followed by continuous ultrasound for 10 minutes.

photocoagulation Use of a laser, such as in treatment of retinal detachment.

photophobia Abnormal sensitivity to light.

photopsia The appearance of bright flashes of light due to the onset of retinal detachment.

physiatrist A physician who specializes in rehabilitative medicine.

physical abuse The use of a physical force, such as hitting, burning, pushing, and molesting the patient, that results in bodily injury.

physical dependence The adaptation manifested by a drug class-specific withdrawal syndrome. Manifestations can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, or administration of an antagonist.

physical therapist (PT, RPT) A member of the rehabilitation health care team who helps the patient achieve mobility and who teaches techniques for performing certain activities of daily living.

piggyback set See *secondary administration set*.

pilonidal cyst A lesion of the sacral area that often has a sinus track extending into deeper tissue structures.

pinna The external ear, which is composed of cartilage covered by skin.

pitting Indentation of the skin; often occurs with edema.

pituitary Cushing's disease Oversecretion of ACTH by the anterior pituitary gland, which causes hyperplasia of the adrenal cortex in both adrenal glands and an excess of most hormones secreted by the adrenal cortex.

placebo Substance or action that produces an effect regardless of its known intrinsic value or specific physical or chemical properties.

placebo effect A patient's favorable response to a placebo.

plantar fasciitis An inflammation of the plantar fascia, which is located in the area of the arch of the foot. It is often seen in athletes, especially runners.

plasma cell A short-lived B-lymphocyte that begins functioning immediately to produce antibodies against sensitizing antigens.

plasmapheresis The separation of plasma from whole blood, after which the blood cells are returned to the patient without the plasma to eliminate antibodies.

pleiotropic Having widespread or numerous effects.

plethoric A flushed appearance of the skin.

pleura The continuous smooth membrane composed of two surfaces that totally enclose the lungs.

pleural effusion Fluid in the pleural space.

pleuritic chest pain A stabbing pain on taking a deep breath.

pleurodesis An inflammation created by instilling a sclerosing agent through a chest tube into the pleural space, which causes the pleura to stick to the chest wall and prevent formation of effusion fluid.

plexus Cluster of nerves.

ploidy The number and appearance of chromosomes; used to describe cancer cells.

pluripotency The unlimited potential of early embryonic cells to mature into any body cell; also called "multipotency" or "totipotency."

pluripotent stem cell The precursor cell involved in the production of red blood cells.

pneumonectomy Removal of an entire lung, including all blood vessels.

pneumothorax Air in the pleural (chest) cavity.

podagra Inflammation of the metatarsophalangeal joint of the great toe.

point of maximal impulse (PMI) See *apical impulse*.

point mutation The substitution of one base for another.

polyarthralgia Aching around multiple joints.

polycystic kidney disease (PKD) An inherited disorder in which fluid-filled cysts develop in the kidneys.

polycythemia An excess of red blood cells.

polycythemia vera (PV) A disease that involves massive production of red blood cells, leukocytes, and platelets.

polydipsia Excessive intake of water.

polymedicine The use of many drugs to treat multiple health problems for older adults.

polymorphism A variation in form.

polymyalgia rheumatica (PMR) A clinical syndrome characterized by stiffness, weakness, aching of the proximal musculature (the shoulder and pelvic girdles), and systemic manifestations such as low-grade fever, arthralgias and stiffness, fatigue, and weight loss.

polymyositis A diffuse inflammatory disease of skeletal (striated) muscle that causes symmetric weakness and atrophy.

polyp An abnormal outgrowth from a mucous membrane.

polypectomy Surgical removal of a polyp, such as a nasal polyp.

polyphagia Excessive eating.

polypharmacy The use of many drugs to treat multiple health problems for older adults.

polyuria Frequent and excessive urination.

pores Openings or spaces.

portal hypertension An abnormal persistent increase in pressure within the portal vein; a major complication of cirrhosis.

portal hypertensive gastropathy A complication that can occur in patients with portal hypertension, with or without esophageal varices. Slow gastric mucosal bleeding may result in chronic slow blood loss, occult positive stools, and anemia.

portal-systemic encephalopathy (PSE) A clinical disorder seen in hepatic failure and cirrhosis; it is manifested by neurologic symptoms and is characterized by an altered level of consciousness, impaired thinking processes, and neuromuscular disturbances; also called "hepatic encephalopathy" and "hepatic coma."

positive deflection In electrocardiography, the flow of electrical current in the heart (cardiac axis) toward the positive pole.

positive inotropic agents Drugs that increase myocardial contractility and are prescribed to improve cardiac output.

positron emission tomography (PET) A diagnostic tool that provides information about the function of the brain, specifically glucose and oxygen metabolism and cerebral blood flow. The patient is injected with the molecule *deoxyglucose*, which is tagged to an isotope. The isotope emits activity in the form of positrons, which are scanned and converted into a color image by a computer.

postanesthesia care unit (PACU) Recovery room.

postcholecystectomy syndrome (PCS) The occurrence of the clinical manifestations of biliary tract disease following cholecystectomy; caused by residual or recurring calculi, inflammation, or stricture of the common bile duct.

post-concussion syndrome A group of clinical manifestations following a concussion that consist of personality changes, irritability, headaches, dizziness, restlessness, nervousness, insomnia, memory loss, and depression.

The prolonged pattern is classified as post-trauma syndrome.

posterior colporrhaphy The surgical procedure to repair a rectocele by strengthening pelvic supports and reducing the bulging.

posterior cord lesion A condition caused by cervical injuries; results from damage to the posterior gray and white matter of the spinal cord. Motor function remains intact, but the patient experiences a loss of vibratory sense, crude touch, and position sensation; this is the opposite of anterior cord syndrome.

posteroanterior Back to front; position for standard chest x-rays.

postherpetic neuralgia Pain that persists after herpes zoster lesions have resolved.

postictal stage Referring to the time immediately after a seizure.

postoperative After surgery.

postpericardiotomy syndrome Symptoms, including pericardial and pleural pain, pericarditis, friction rub, elevated temperature and white blood cell count, and dysrhythmias, that occur in patients after cardiac surgery; may occur days to weeks after surgery and seems to be associated with blood that remains in the pericardial sac.

postrenal failure Decrease in renal function related to an obstruction in the flow of urine. It can progress to acute renal failure.

postural (orthostatic) hypotension A decrease of more than 20 mm Hg of systolic pressure or more than 10 mm Hg of diastolic pressure, with a 10% to 20% increase in heart rate; patients may report dizziness or lightheadedness when they move from a lying to a sitting or standing position.

post-void residual (PVR) The amount of urine remaining in the bladder within 20 minutes after voiding.

potency The ability to have and sustain an erection.

PQRST A mnemonic (memory device) that may help in the current problem assessment of patients with gastrointestinal tract disorders. The letters represent the following areas **P**, precipitating or palliative (What brings it on? What makes it better or worse?); **Q**, quality or quantity (How does it look, feel, or sound?); **R**, region or radiation (Where is it? Does it spread anywhere?); **S**, severity scale (How bad is it [on a scale of 1 to 10]? Is it getting better, worse, or staying the same?); **T**, timing (Onset, duration, and frequency?).

PR interval In the electrocardiogram, the interval measured from the beginning of the P wave to the end of the PR segment; represents the time required for atrial depolarization as well as impulse delay in the atrioventricular node and travel time to the Purkinje fibers.

PR segment In the electrocardiogram, the isoelectric line from the end of the P wave to the beginning of the QRS complex, when the electrical impulse is traveling through the atrioventricular node, where it is delayed.

prandial insulin secretion The increased levels of insulin that are secreted after eating.

Within 10 minutes of eating, an early burst of insulin secretion occurs, which is followed by an increasing insulin release that lasts as long as hyperglycemia is present.

prealbumin (PAB) A protein secreted by the liver that binds thyroxine.

precipitation The formation of large, insoluble antigen-antibody complexes during the antibody-binding process.

prediabetes An impaired fasting glucose (IFG) or impaired glucose tolerance (IGT).

pre-emptive analgesia A technique to decrease postoperative pain and the requirements for analgesia, improve morbidity, and decrease hospital stay by administering local anesthetics, opioids, and nonsteroidal anti-inflammatory drugs in the preoperative, intraoperative, or postoperative period.

prehospital care provider Typically, any of the first caregivers encountered by the patient if he or she is transported to the emergency department by an ambulance or helicopter.

prehypertension A blood pressure category that includes blood pressure readings of 120 to 139 mm Hg systolic or 80 to 89 mm Hg diastolic. Prehypertensive patients are at a higher risk for the development of hypertension.

preictal phase Referring to events that a patient experiences before a seizure, such as the presence of an aura.

preinfarction angina Chest pain that occurs in the days or weeks before a myocardial infarction.

preload The degree of myocardial fiber stretch at the end of diastole and just before contraction; determined by the amount of blood returning to the heart from both the venous system (right heart) and the pulmonary system (left heart).

premature atrial complex (PAC) In the electrocardiogram, an early complex that occurs when atrial tissue becomes irritable. This ectopic focus fires an impulse before the next sinus impulse is due, thus usurping the sinus pacemaker. The premature P wave from the atrial focus is early and has a shape different from that of the P wave generated from the sinus node.

premature complex In the electrocardiogram, an early complex that occurs when a cardiac cell or cell group other than the sinoatrial node becomes irritable and fires an impulse before the next sinus impulse is generated. After the premature complex, there is a pause before the next normal complex, which creates an irregularity in the rhythm.

premature ventricular complex (PVC) In the electrocardiogram, an early ventricular complex is followed by a pause that results from increased irritability of ventricular cells. The QRS complexes may be unifocal or uniform (of the same shape), or multifocal or multiform (of different shapes).

premenstrual dysphoric disorder (PMDD) A more disabling and severe form of premenstrual syndrome.

premenstrual syndrome (PMS) A collection of symptoms that occur in the 2 weeks before menstruation and are followed by relief with menses and a symptom-free phase. Symptoms may include emotional, physical, and cognitive manifestations such as irritability, breast tenderness, and short-term memory problems.

preoperative Before surgery.

prepuce The foreskin of the penis.

prerenal failure Condition that causes inadequate kidney perfusion; can progress to acute renal failure.

presbycusis The loss of hearing, especially for high-pitched sounds; occurs as a result of aging.

presbyopia An age-related impairment of vision characterized by a loss of lens elasticity and the ability of the eye to accommodate. The near point of vision increases, and near objects must be placed farther from the eye to be seen clearly.

presence A type of communication that consists of listening and acknowledging the legitimacy of the patient's and/or family's pain.

pressure ulcer Tissue damage caused when the skin and underlying soft tissue are compressed between a bony prominence and an external surface for an extended period; commonly occurs over the sacrum, hips, and ankles.

pretibial Pertaining to the front of the leg below the knee.

pretibial myxedema Dry, waxy swelling of the front surfaces of the lower legs.

preventive therapy drugs For asthma, drugs that are used every day regardless of symptoms to change airway responsiveness and prevent asthma attacks from occurring.

priapism An abnormal, long-maintained erection without sexual desire, which causes the penis to become large, hard, and painful. It can occur from neural, vascular, or pharmacologic causes.

primary angle-closure glaucoma A form of glaucoma characterized by a narrowed angle and forward displacement of the iris so that movement of the iris against the cornea narrows or closes the chamber angle, obstructing the outflow of aqueous humor. It can have a sudden onset and is an emergency; also called "closed-angle glaucoma," "narrow-angle glaucoma," or "acute glaucoma."

primary arthroplasty A total joint arthroplasty procedure that has been performed for the first time.

primary epilepsy Epilepsy that is not associated with any identifiable brain lesion or other specific cause; however, genetic factors most likely play a role in its development.

primary gout The most common type of gout; results from one of several inborn errors of purine metabolism.

primary lesions In describing skin disease, the initial reaction to a problem that alters one of the structural components of the skin.

primary open-angle glaucoma (POAG) The most common form of primary glaucoma;

characterized by reduced outflow of aqueous humor through the chamber angle. Because the fluid cannot leave the eye at the same rate it is produced, intraocular pressure gradually increases.

primary prevention Strategies used to avoid or delay the actual occurrence of a specific disease.

primary progressive multiple sclerosis A type of multiple sclerosis (MS) that involves a steady and gradual neurologic deterioration without remission of symptoms. Patients with this type of MS are usually between 40 and 60 years of age at onset of the disease and experience progressive disability with no acute attacks.

primary survey Priorities of care addressed in order of immediate threats to life as part of the initial assessment in the emergency department. Survey is based on an “ABC” mnemonic with “D” and “E” added for trauma patients: airway/cervical spine (A), breathing (B), circulation (C), disability (D), and exposure (E).

primary tumor The original tumor, usually identified by the tissue from which it arose (parent tissue), such as in breast cancer or lung cancer.

progressive multifocal leukoencephalopathy (PML) Rare disease affecting the white matter of the brain caused by a virus that attacks the cells that make myelin; occurs most often in patients who are immunosuppressed.

progressive stage of shock The stage of shock that occurs with a sustained decrease in mean arterial pressure, when compensatory mechanisms are functioning but are no longer delivering sufficient oxygen, even to vital organs.

progressive-relapsing multiple sclerosis A type of multiple sclerosis (MS) that occurs in only 5% of patients with MS. It is characterized by the absence of periods of remission, and the patient's condition does not return to baseline. Progressive cumulative symptoms and deterioration occur over several years.

proinsulin A precursor of insulin that includes the alpha and beta chains of the insulin molecule.

projected pain Pain that occurs along a specific nerve or nerves.

proliferative diabetic retinopathy (PDR) A form of retinopathy associated with diabetes mellitus in which a network of fragile new blood vessels develops, leaking blood and protein into surrounding tissue. The new blood vessels are stimulated by retinal hypoxia that results from poor capillary perfusion of the retinal tissues. New blood vessels grow in the retina, onto the iris, and into the back of the vitreous. The vitreous contracts and pulls away from the retina, causing blood vessels to break and bleed into the vitreous.

promoter In oncology, a substance that promotes or enhances growth of the initiated cancer cell; may be a hormone, drug, or chemical.

pronator drift Occurs in a patient with muscle weakness due to cerebral or brainstem reasons. The arm on the weak side tends to fall, or “drift,” with the palm pronating (turning inward) after the patient has closed his or her eyes and held the arms perpendicular to the body with the palms up for 15 to 30 seconds; part of the neurologic assessment.

prophylactic mastectomy Highly controversial practice of surgically removing the breast in order to reduce the risk of breast cancer.

prophylactic surgery Surgery done to remove “at-risk” tissue to prevent cancer development.

proportional pulse pressure A measurement of cardiac output that is calculated from blood pressure measurements, as follows: subtract diastolic from systolic blood pressure, and divide the result by systolic blood pressure. A proportional pulse pressure less than 25% indicates severely compromised cardiac output.

proprioception Position sense.

proprioceptive Awareness of body position.

prosopagnosia The inability to recognize oneself and other familiar faces; occurs in patients in the later stages of Alzheimer's disease.

prostaglandins Chemicals that are produced in the cells and cause inflammation and swelling.

prostate gland A large accessory gland of the male reproductive system. It secretes a milky alkaline fluid that adds bulk to the semen, enhances sperm motility, and neutralizes acidic vaginal secretions.

prostatectomy Surgical removal of the prostate.

prostate-specific antigen (PSA) A glycoprotein produced solely by the prostate. The normal blood level of PSA is less than 4 ng/mL; levels are higher in patients with increased prostatic tissue as a result of benign prostatic hyperplasia, prostatic infarction, prostatitis, and prostate cancer. Levels associated with prostate cancer are usually much higher than those occurring with other prostate tissue enlargement.

prostatitis Inflammation of the prostate.

prostatodynia Pain in the prostate with manifestations of prostatitis but no inflammation of the prostate and a negative urine culture.

prostration Extreme exhaustion.

protein-calorie malnutrition (PCM) A disorder of nutrition that may present in three forms: marasmus, kwashiorkor, and marasmic-kwashiorkor; also called “protein-energy malnutrition.”

protein-energy malnutrition (PEM) See *protein-calorie malnutrition*.

protein synthesis The process by which genes are used to make the proteins needed for physiologic function.

proteinuria The presence of protein in the urine.

proteolysis The breakdown of proteins to provide fuel for energy when liver glucose is unavailable.

proton-pump inhibitor (PPI) A group of drugs that inhibit the proton pump in the stomach to decrease gastric acid production.

pruritus An unpleasant itching sensation.

pseudoaddiction An iatrogenic syndrome created by the undertreatment of pain and characterized by patient behaviors such as anger and escalating demands for more or different medications; results in suspicion and avoidance by staff. Pseudoaddiction can be distinguished from true addiction because the behaviors resolve when pain is effectively treated.

pseudogout A disease that mimics the clinical manifestations of gout; however, the crystals deposited in the joints are calcium pyrophosphate, not sodium urate.

psoriatic arthritis (PsA) A syndrome of inflammatory arthritis associated with psoriasis, the skin condition characterized by a scaly, itchy rash.

psychiatric crisis nurse team An emergency department specialty team whose nurses interact with patients and families in crisis.

psychotropic drugs Antipsychotic and neuroleptic drugs. These are appropriately given to patients with emotional and behavioral health problems (e.g., hallucinations and delusions) that accompany dementia but are sometimes inappropriately used for agitation, combativeness, or restlessness. They are considered chemical restraints because they decrease mobility and patients' ability to care for themselves.

ptosis Drooping of the eyelid.

pulmonary artery occlusive pressure (PAOP)
See *pulmonary artery wedge pressure*.

pulmonary artery wedge pressure (PAWP) Measurement of pressure in the left atrium using a balloon-tipped catheter introduced into the pulmonary artery. When the balloon at the catheter tip is inflated, the catheter advances and wedges in a branch of the pulmonary artery. The tip of the catheter is able to sense pressures transmitted from the left atrium, which reflect left ventricular end-diastolic pressure; also called “pulmonary artery occlusive pressure.”

pulmonary autograph The relocation of the patient's own pulmonary valve to the aortic position for aortic valve replacement (Ross procedure).

pulmonary embolism (PE) A collection of particulate matter, most commonly a blood clot, that enters venous circulation and lodges in the pulmonary vessels, obstructing pulmonary blood flow and leading to decreased systemic oxygenation, pulmonary tissue hypoxia, and potential death.

pulmonic valve The semilunar valve of the heart that separates the right ventricle from the pulmonary artery.

pulse deficit The difference between the apical and peripheral pulses.

pulse pressure The difference between the systolic and diastolic pressures.

pulse therapy Any therapy given at a high dose for a short duration.

pulsus alternans A type of pulse in which a weak pulse alternates with a strong pulse despite a regular heart rhythm; seen in patients with severely depressed cardiac function.

pump A pole-mounted or portable device that pumps medication or fluid under pressure during infusion therapy.

pump failure See *heart failure*.

punctum The opening through which tears drain; located at the nasal side of the eyelid edges.

pupil The opening through which light enters the eye; located in the center of the iris of the eye.

pure tones Tones generated by an audiometer to determine hearing acuity.

Purkinje cells In the cardiac conduction system, the cells that make up the bundle of His, bundle branches, and terminal Purkinje fibers. These cells are responsible for the rapid conduction of electrical impulses throughout the ventricles, leading to ventricular depolarization and subsequent ventricular muscle contraction.

purpura Purple patches on the skin that may be caused by blood disorders, vascular abnormalities, or trauma.

pyelolithotomy The surgical removal of a stone from the kidney.

pyelonephritis A bacterial infection in the kidney and renal pelvis (the upper urinary tract).

pyloromyotomy An incision through the serosa and muscularis of the pylorus, down to the mucosa; created to prevent gastric motility disturbances in patients who have undergone esophagectomy.

pyogenic liver abscess A liver abscess resulting from bacterial infection by *Escherichia coli* and *Klebsiella*, *Enterobacter*, *Salmonella*, *Staphylococcus*, and *Enterococcus* species. A pyogenic abscess is generally solitary and is confined to the right lobe, but occasionally abscesses are multiple.

pyramid The fan-shaped structures that constitute the medulla of the kidney. Each kidney has 12 to 18 pyramids.

pyuria The presence of white blood cells (pus) in the urine.

Q

QRS complex In the electrocardiogram, the portion consisting of the Q, R, and S waves, representing ventricular depolarization.

QRS duration In the electrocardiogram, the time required for depolarization of both ventricles; measured from the beginning of the QRS complex to the J point (the junction where the QRS complex ends and the ST segment begins).

QT interval In the electrocardiogram, the time from the beginning of the QRS complex to the end of the T wave. It represents the total time required for ventricular depolarization and repolarization.

quadriceps-setting exercise Postoperative leg exercise performed by straightening the

legs and pushing the back of the knees into the bed.

quadrigeminy A type of premature complex consisting of a repetitive four-beat pattern; usually occurs as three sequential normal complexes followed by a premature complex and a pause, with the same pattern repeating itself in a four-beat pattern.

quadripareisis Weakness that involves all four extremities; seen with cervical spinal cord injury.

qualitative question A clinical question that focuses on the meanings and interpretations of human phenomena or experience of people and usually analyzes the content of what a person says during an interview or what a researcher observes.

quality improvement A competency that nurses can achieve by using data to monitor the outcomes of care processes and using improvement methods to design and test changes to continuously improve the quality and safety of health care systems.

quantitative question A clinical question that asks about the relationship between or among defined, measurable phenomena and includes statistical analysis of information that is collected to answer a question.

R

Rad Older acronym for “radiation absorbed dose.”

radiating pain Diffuse, unlocalized pain around the site of origin.

radiation dose The amount of radiation absorbed by the tissue.

radiation exposure The amount of radiation delivered to a tissue during radiation therapy.

radiation proctitis Rectal mucosa inflammation that results from external beam radiation therapy.

radical cystectomy Removal of the bladder and surrounding tissue with urinary diversion.

radical vulvectomy The surgical removal of the entire vulva skin, labia, clitoris, subcutaneous tissues, and possibly inguinal and femoral node dissection.

radicular Referring to a nerve root.

radiculopathy Referring to radicular pain; spinal nerve root involvement.

radiofrequency ablation The use of heat to achieve permanent ablation of nerve roots.

radiofrequency catheter ablation An invasive procedure that uses radiofrequency waves to abolish an irritable focus that is causing a supraventricular or ventricular tachyarrhythmia.

Rapid Response Team Team of critical care experts that save lives and decrease the risk for harm by providing care to patients before a respiratory or cardiac arrest occurs. Also called “Medical Emergency Team.”

rebound headache Headache that occurs as a side effect of a drug that has relieved an initial migraine headache; also called “medication overuse headache.”

recall memory Recent memory, which can be tested during the history taking by asking about items such as the dates of clinic or physician appointments.

receptive aphasia A type of aphasia caused by injury to Wernicke’s area in the temporoparietal area of the brain and characterized by an inability to understand the spoken and written word; both reading and writing ability are equally affected. Although the patient can talk, the language is often meaningless and neologisms (made-up words) are common parts of speech. Also called “Wernicke’s aphasia” or “sensory aphasia.”

reconstructive plastic surgery Type of plastic surgery that corrects or improves functional defects that have occurred as a result of congenital problems, trauma and scarring, or other types of therapy.

reconstructive surgery Surgery done to increase function, enhance appearance, or both; also called “rehabilitative surgery.”

recreational exercise A type of exercise that includes hobbies and sports, with no planned purpose other than relaxation.

recreational therapist A member of the health care team who works to help patients continue or develop hobbies or interests; also called “activity therapist.”

rectocele A protrusion of the rectum through a weakened vaginal wall.

red reflex A reflection of light on the retina seen as a red glare during ophthalmoscopic examination. An absent red reflex may indicate a lens opacity or cloudiness of the vitreous.

redirection An intervention to help with communication problems in patients with dementia; consists of attracting the patient’s attention before conversing, keeping the environment as free of distractions as possible, and speaking directly to the patient in a distinct manner using clear and short sentences.

reducible hernia A hernia that can be placed back into the abdominal cavity by gentle pressure.

reduction mammoplasty Breast reduction surgery in which the surgeon removes excess breast tissue and then repositions the nipple and remaining skin flaps to produce an optimal cosmetic effect.

Reed-Sternberg cell A specific cancer cell type, found in lymph nodes, that is a marker for Hodgkin’s lymphoma.

re-epithelialization In partial-thickness (superficial) wounds involving damage to the epidermis and upper layers of the dermis, a form of healing by means of the production of new skin cells by undamaged epidermal cells in the basal layer of the dermis.

refeeding syndrome Life-threatening metabolic complication that can occur when nutrition is restarted for a patient who is in a starvation state.

referred pain Perceived pain in an area distant from the site of painful stimuli.

reflex arc A closed circuit of spinal and peripheral nerves that requires no control by the brain.

reflex bladder Incontinence characterized by sudden, gushing voids, usually without completely emptying the bladder; caused by neurologic problems affecting the upper motor neuron, such as with spinal cord injuries above the twelfth thoracic vertebra; also called “spastic bladder.”

reflex sympathetic dystrophy (RSD) See *complex regional pain syndrome*.

reflux Reverse or backward flow.

reflux esophagitis Damage to the esophageal mucosa, often with erosion and ulceration, in patients with gastroesophageal reflux disease.

refract To cause to bend.

refraction The bending of light rays.

refractory stage The stage of shock that occurs when too much cell death and tissue damage result from too little oxygen reaching the tissues; the vital organs have overwhelming damage, and the body is unable to respond effectively to interventions. Formerly called the “irreversible stage.”

regional anesthesia A type of local anesthesia that blocks multiple peripheral nerves in a specific body region.

regurgitation Flowing in the opposite direction from normal, as the occurrence of warm fluid traveling up the throat, unaccompanied by nausea, in the patient with gastroesophageal reflux disease.

rehabilitation The process of learning to live with chronic and disabling conditions by returning the patient to the fullest possible physical, mental, social, vocational, and economic capacity.

rehabilitation case manager Nurse or other health care professional who coordinates health care for patients undergoing rehabilitation in home or acute care settings.

rehabilitation nurse Nurse who coordinates the efforts of health care team members for patients undergoing rehabilitation in the inpatient setting; may be designated as the patient’s case manager.

rehabilitative surgery See *reconstructive surgery*.

relapsing-remitting multiple sclerosis A type of multiple sclerosis that occurs in 85% of cases and is characterized by a mild or moderate course, depending on the degree of disability. Relapses develop over 1 to 2 weeks and resolve over 4 to 8 months, after which the patient returns to baseline.

religion The formal expression of spirituality.

relocation stress syndrome Physiologic or psychosocial distress following transfer from one environment to another, such as after admission to a hospital or nursing home; also called “relocation trauma.”

reminiscence The process of randomly reflecting on memories of events in one’s life.

remote memory Long-term memory of events; can be tested by asking patients about their birth date, schools attended, city of birth, or anything from the past that can be verified.

renal calculi Kidney stones.

renal colic Severe pain associated with distention or spasm of the ureter, such as with an obstruction or the passing of a stone; the pain radiates into the perineal area, groin, scrotum, or labia. Pain may be intermittent or continuous and may be accompanied by pallor, diaphoresis, and hypotension.

renal columns Cortical tissue that dips into the interior of the kidney and separates the pyramids in the medulla; also called “columns of Bertin.”

renal cortex The outermost layer of functional kidney tissue lying beneath the renal capsule.

renal osteodystrophy The problems in bone metabolism and structure caused by renal failure-induced hypocalcemia and hyperphosphatemia.

renal pelvis The expansion from the upper end of the ureter into which the calices of the kidney open.

renal threshold The limit to the amount of glucose that the kidney can reabsorb as glucose is filtered from the blood; also called the “transport maximum.”

renin A hormone that is produced in the juxtaglomerular complex of the kidney and helps regulate blood flow, glomerular filtration rate, and blood pressure. Renin is secreted when sensing cells (macula densa) in the distal convoluted tubule sense changes in blood volume and pressure.

repetitive stress injury (RSI) Injury caused by repeated movements of the same part of the body (e.g., carpal tunnel syndrome).

replication The reproduction of DNA that occurs each time a cell divides.

repolarization A return to baseline after depolarization.

rescue drugs For asthma, drugs that are used to actually stop an asthma attack once it has started.

reservoir In health care, a source of infectious agents. Animate reservoirs include people, animals, and insects. Inanimate reservoirs include environmental sources and medical equipment. Community reservoirs include sewage, contaminated water, and improperly handled foods.

resistin A hormone produced by fat cells that creates resistance to insulin activity.

resorption In referring to bone, the loss of bone minerals and density; the release of free calcium from bone storage sites directly into the extracellular fluid.

restorative aid A member of the health care team, often with the nursing department, who assists the therapists, especially in the long-term care setting.

restraint Any device (physical restraint) or drug (chemical restraint) that prevents the patient from moving freely.

restrictive cardiomyopathy A form of cardiomyopathy that restricts the filling of the ventricles; a type of lung disease that prevents good expansion and recoil of the gas exchange unit.

restrictive disorders Disorders that prevent good expansion and recoil of the gas exchange unit.

restrictive lung disorder Any lung disorder that prevents good expansion and recoil of the gas exchange unit.

resurfacing Regrowth of new skin cells across the open area of a wound as it heals.

resuscitation phase The first phase of a burn injury, beginning at the onset of injury and continuing to about 48 hours.

rete pegs The fingers of epidermal tissue that project into the dermis.

reticular activating system (RAS) Special cells throughout the brainstem that constitute the system that controls awareness and alertness.

retina The innermost layer of the eye, made up of sensory receptors that transmit impulses to the optic nerve. It contains blood vessels and two types of photoreceptors called “rods” and “cones.” Rods work at low light levels and provide peripheral vision; cones are active at bright light levels and provide color and central vision.

retinal detachment Separation of the retina from the epithelium.

retinal hole A break in the retina; can be caused by trauma or can occur with aging.

retinal tear Jagged and irregularly shaped break in the retina resulting from traction on the retina.

retinitis Inflammation of the retina.

retinopathy Inflammation of the retina; also used as a general term for vision problems.

retrograde Going against the normal direction of flow.

retrograde ejaculation Condition in which semen flows backwards into the bladder so that only a small amount is ejaculated from the penis.

retroviruses The family of viruses that includes the human immune deficiency virus.

reversible ischemic neurologic deficit (RIND) A type of transient focal neurologic dysfunction resulting from a brief interruption in cerebral blood flow; symptoms last longer than 24 hours but less than a week.

revision arthroplasty Surgical replacement of a prosthesis that has loosened and is causing pain.

rhabdomyolysis The breakdown or disintegration of muscle tissue; associated with excretion of myoglobin in the urine.

rheumatic carditis Inflammatory lesions in the heart due to a sensitivity response that develops after an upper respiratory tract infection with group A beta-hemolytic streptococci, which occurs in about 40% of patients with rheumatic fever. Inflammation results in impaired contractile function of the myocardium, thickening of the pericardium, and valvular damage.

rheumatic disease Any disease or condition involving the musculoskeletal system.

rheumatoid arthritis (RA) A chronic, progressive, systemic, inflammatory autoimmune disease process that primarily affects the

synovial joints; one of the most common connective tissue diseases and the most destructive to the joints.

rhinitis An inflammation of the nasal mucosa.

rhinitis medicamentosa Nasal congestion from overuse of nose drops or sprays.

rhinoplasty A surgical reconstruction of the nose done for cosmetic purposes and improvement of airflow.

rhinorrhea Watery drainage from the nose; a “runny” nose.

rhizotomy Surgical technique in which sensory nerve roots are destroyed where they enter the spinal cord; used to interrupt the transmission of pain.

rhytidectomy Plastic surgery to eliminate wrinkles from the facial skin; commonly known as a “face lift.”

rickets Vitamin D deficiency in children.

right-sided heart (ventricular) failure The inability of the right ventricle to empty completely, resulting in increased volume and pressure in the systemic veins and systemic venous congestion with peripheral edema.

rigidity Abnormal resistance to passive movement of the extremities, an early sign of Parkinson disease.

rigors Severe chills.

Romberg sign Swaying or falling when the patient is standing with arms at the sides, feet and knees close together, and eyes closed; a test of equilibrium in neurologic assessment.

rotation A mechanism of injury in which the head is turned excessively beyond the normal range.

rubor Dusky red discoloration of the skin.

rugae Folds, as of a mucous membrane.

S

S phase The phase of cell division in which the cell doubles its deoxyribonucleic acid (DNA) content by separating the double strands of DNA and building a new strand complementary to the original strand (DNA synthesis).

S₃ gallop The third heart sound; an early diastolic filling sound that indicates an increase in left ventricular pressure and may be heard on auscultation in patients with heart failure.

salpingitis Infection of the fallopian tube.

sanguineous Having a bloody appearance.

sarcoidosis A granulomatous disorder of unknown cause that can affect any organ but most often involves the lung.

SBAR Acronym for a formal method of communication between two or more members of the health care team. It is used most often when there is an unmet patient need or problem but can also be used to communicate continuing care issues when a patient is discharged from one agency to another. It consists of four steps **S**ituation, **B**ackground, **A**ssessment, **R**ecommendation.

scabies A contagious skin disease caused by mite infestations.

sclera The external white layer of the eye.

scleroderma See *systemic sclerosis*.

sclerosing agent An irritant that causes inflammation; often used to relieve pleural effusion.

sclerotherapy The injection of a sclerosing agent via a catheter, usually in an endoscopic procedure, to stop variceal bleeding.

sclerotic Hard, or hardening.

scoliosis An abnormal lateral curve in the spine, which normally should be a straight vertical line.

scotoma Blind spot in the visual field.

scrotum A thin-walled, fibromuscular pouch that lies behind the penis and is suspended below the pubic bone. This pouch protects the testes, epididymis, and vas deferens in a space that is slightly cooler than inside the abdominal cavity.

seborrhea Excessive secretion of sebum, resulting in greasy, itchy scaling.

sebum A mildly bacteriostatic, fat-containing substance produced by the sebaceous glands. Sebum lubricates the skin and reduces water loss from the skin surface.

second intention healing Healing of deep tissue injuries or wounds with tissue loss in which a cavity-like defect requires gradual filling of the dead space with connective tissue, which prolongs the repair process.

secondary administration set A short conduit that is attached to the primary administration set at a Y-injection site and is used to deliver intermittent medications; also called a “piggyback set.”

secondary gout Gout involving hyperuricemia.

secondary hypertension Elevated blood pressure that is related to a specific disease (e.g., kidney disease) or medication (e.g., estrogen).

secondary lesion Describing skin disease in terms of changes in the appearance of the primary lesion. These changes occur with progression of an underlying disease or in response to a topical or systemic therapeutic intervention.

secondary prevention Early detection of a disease or condition, sometimes before signs and symptoms are evident, to prevent or limit permanent disability or death.

secondary progressive multiple sclerosis A type of multiple sclerosis that begins with a relapsing-remitting course and later becomes steadily progressive. Attacks and partial recoveries may continue to occur.

secondary seizure Non-epileptic seizure that results from an underlying brain lesion, most commonly a tumor or trauma.

secondary survey In the emergency department, a more comprehensive head-to-toe assessment performed to identify other injuries or medical issues that need to be managed or that might impact the course of treatment.

secondary tumor Additional tumor that is established when cancer cells move from the primary location to another area in the body; also called “metastatic tumor.”

second-look surgery Surgery done to assess the disease status in patients who have been

treated and have no symptoms of remaining cancer tumor.

segmentectomy A lung resection (segmental resection) that includes the bronchus, pulmonary artery and vein, and tissue of the involved lung segment or segments, which are divisions of lobes.

seizure An abnormal, sudden, excessive, uncontrolled electrical discharge of neurons within the brain that may result in an alteration in consciousness, motor or sensory ability, and/or behavior. A single seizure may occur for no known reason; however, seizures may be due to a pathologic condition of the brain, such as a tumor.

self-determination An individual sense of autonomy; capable of making informed decisions about care. Also called “self-management.”

self-management See *self-determination*.

self-tolerance In immunology, the ability to recognize self cells versus non-self cells, which is necessary to prevent healthy body cells from being destroyed along with invading cells.

semicircular canals Within the inner ear, tubes made of cartilage that contain fluid and hair cells and are connected to the sensory nerve fibers of the vestibular portion of the eighth cranial nerve. The fluid and hair cells within the canals help maintain the sense of balance.

sensitivity The likelihood that infecting bacterial organisms will be killed or stopped by a particular antibiotic drug. Sensitivity is determined by testing different antibiotics against the organisms. Organisms are “sensitive” if the antibiotic is effective in stopping their growth; organisms are “resistant” if the antibiotic is not effective.

sensorineural hearing loss Hearing loss that results from a defect in the cochlea, the eighth cranial nerve, or the brain itself. Exposure to loud noises and music may cause this type of hearing loss as a result of damage to the cochlear hair cells.

sensory Facilitating sensation.

sensory aphasia See *receptive aphasia*.

sepsis Systemic infection.

septic shock The type of shock that occurs when large amounts of toxins and endotoxins produced by bacteria are released into the blood, causing a whole-body inflammatory reaction.

septicemia Systemic disease associated with sepsis; the presence of pathogens in the blood.

sequestrum A piece of necrotic bone that has separated from surrounding bone tissue; a common complication of osteomyelitis.

serologic testing Laboratory testing that is performed to identify pathogens by detecting antibodies to the organism.

serositis Inflammation of a serous membrane, such as the pleura or peritoneum.

serous Having a serum-like appearance, or yellow color.

serum sickness A type III hypersensitivity reaction that develops first as a skin rash and occurs within 3 to 21 days of

the administration of antivenin (Crotalidae) polyvalent. This allergic response is often accompanied by other manifestations such as fever, arthralgias (joint pains), and pruritus (itching).

severe acute respiratory syndrome (SARS)

An easily spread respiratory infection first identified in China in November 2002. At first appearing as an atypical pneumonia, it is caused by a new, more virulent form of coronavirus, and there is no known effective treatment.

severe sepsis The progression of sepsis with an amplified inflammatory response.

sex chromosomes The pair of chromosomes containing the genes for sexual differentiation in humans. In males, the sex chromosomes are an X and a Y; in females, the sex chromosomes are two Xs.

sexually transmitted diseases (STDs) Any of a group of diseases caused by infectious organisms that have been passed from one person to another through intimate contact. Some organisms that cause these diseases are transmitted only through sexual contact. Other organisms are transmitted by parenteral exposure to infected blood, fecal-oral transmission, intrauterine transmission to the fetus, and perinatal transmission from mother to neonate.

SHARE Acronym standing for **S**tandardize critical content, **H**ardwire within your system, **A**llow opportunity to ask questions, **R**einforce quality and measurement, **E**ducate and coach.

shift to the left An increased number of immature neutrophils found on a differential count in patients with infections; can be characterized by changes in percentages of different types of leukocytes.

shock The whole-body response to poor tissue oxygenation. Any problem that impairs oxygen delivery to tissues and organs can start the syndrome of shock and lead to a life-threatening emergency.

short peripheral catheter A catheter that consists of a plastic cannula built around a sharp stylet for venipuncture, which extends slightly beyond the cannula and is advanced into the vein.

sialagogue An agent that stimulates the flow of saliva.

simple fracture See *closed fracture*.

simple partial seizure A type of partial seizure in which the patient remains conscious, often reporting an aura (e.g., perception of an offensive smell) before the seizure occurs. Characterized by unilateral movement of an extremity, unusual sensations, and autonomic or psychic symptoms. Autonomic changes include a change in heart rate, skin flushing, and epigastric discomfort.

single-photon emission computed tomography (SPECT) A diagnostic tool using a radiopharmaceutical (agent that enables radioisotopes to cross the blood-brain barrier) that is administered by IV injection, after which the patient is scanned.

sinoatrial (SA) node In the cardiac conduction system, the primary pacemaker of the heart; located close to the epicardial surface of the right atrium near its junction with the superior vena cava. It can spontaneously and rhythmically generate electrical impulses at a rate of 60 to 100 beats/min; also called the "sinus node."

sinus arrhythmia A variant of normal sinus rhythm that results from changes in intrathoracic pressure during breathing; heart rate increases slightly during inspiration and decreases slightly during exhalation. Atrial and ventricular rates are between 60 and 100 beats/min, and atrial and ventricular rhythms are irregular.

sinus bradycardia A cardiac dysrhythmia caused by a decreased rate of sinus node discharge, with a heart rate that is less than 60 beats/min.

sinusitis An inflammation of the mucous membranes of the sinuses.

Sjögren's syndrome In patients with advanced rheumatoid arthritis, the triad of dry eyes, dry mouth, and dry vagina caused by the obstruction of secretory ducts and glands by inflammatory cells and immune complexes.

skin fold measurement Measurement that estimates body fat.

skinning vulvectomy The surgical removal of superficial vulvar skin (without removal of the clitoris) and the replacement of removed skin with split-thickness grafts.

sleep apnea A breathing disruption during sleep that lasts at least 10 seconds and occurs a minimum of 5 times in an hour.

sliding board Alternative transfer technique for a patient who cannot bear weight but who has balance skills.

smart pump An infusion pump with dosage calculation software.

smegma A white, cheesy secretion from the sebaceous glands in the glans; may accumulate under the foreskin of the penis. This secretion is not present in the circumcised male.

social worker Member of the health care team who helps patients identify support services and resources and who coordinates transfers to or discharges from the rehabilitation setting.

sodium (Na⁺) A mineral that is the major cation in the extracellular fluid and maintains extracellular fluid (ECF) osmolarity.

solubility The degree to which a solute dissolves in water.

solute A particle dissolved or suspended in the water portion (solvent) of body fluids; a solution consists of a solute and a solvent.

solvent The water portion of fluids.

Somogyi's phenomenon In the patient with diabetes, morning hyperglycemia from the effective counterregulatory response to nighttime hypoglycemia. Treat by ensuring adequate dietary intake at bedtime and by evaluating the insulin dose and exercise programs to prevent conditions that lead to hypoglycemia.

spastic bladder See *reflex bladder*.

spastic paralysis Paralysis of a part of the body that is characterized by spasticity of muscles due to hypertonia; may be seen in the patient who has experienced a brain attack.

specialized nutritional support (SNS) Total nutritional intake orally or intravenously with commercially prepared products (either total enteral nutrition or total parenteral nutrition).

speech-language pathologist (SLP) A member of the rehabilitation health care team who evaluates and retrains patients with speech, language, or swallowing problems.

spermatogenesis Normal sperm production and maturation.

sphincter of Oddi The sheath of muscle fibers surrounding the papillary opening of the duodenum.

sphincterotomy A procedure for opening a sphincter.

spica cast A type of cast that encases a portion of the trunk and one or two extremities; contrasted with a body cast, which encircles the trunk of the body.

spider angiomas Vascular lesions with a red center and radiating branches; also called "telangiectasias," "spider nevi," or "vascular spiders."

spinal fusion (arthrodesis) A surgical procedure to stabilize the spine after repeated laminectomies have been unsuccessful. Chips of bone are removed (typically from the iliac crest) or are obtained from donor bone; the chips are grafted between the vertebrae for support and to strengthen the back.

spinal shock See *spinal shock syndrome*.

spinal shock syndrome Loss of reflex activity below the level of a spinal lesion; occurs immediately after injury as a result of disruption in the communication pathways between the upper motor neurons and the lower motor neurons; also called "spinal shock."

spinal stenosis Narrowing of the spinal canal; typically seen in people older than 60 years.

spirituality The connection to self, others, the environment, and a "higher power."

spiritual counselor Counselor who specializes in spiritual assessments and care, usually a member of the clergy.

splenectomy Surgical removal of the spleen.

splenomegaly Enlargement of the spleen.

splint Any object or device that extends to the joints above and below a fracture to immobilize it.

splinter hemorrhage Black longitudinal line or small red streak on the distal third of the nail bed; seen in patients with infective endocarditis.

spondee Two-syllable words in which there is generally equal stress on each syllable, such as *airplane*, *railroad*, and *cowboy*; used in testing speech reception threshold.

spondylolisthesis Condition in which one vertebra slips forward on the one below it, often as a result of spondylolysis. This problem causes pressure on the nerve roots, leading to pain in the lower back and into the buttocks.

spondylolysis A defect in one of the vertebrae; usually found in the lumbar spine.

spontaneous bacterial peritonitis (SBP) Bacterial infection of the abdominal peritoneum caused by ascites; often seen in patients with cirrhosis of the liver.

spore An encapsulated, inactive organism.

sprain Excessive stretching of a ligament.

ST segment In the electrocardiogram, the line (normally isoelectric) representing early ventricular repolarization. It occurs from the J point to the beginning of the T wave.

staging System of classifying clinical aspects of a cancer tumor.

Standard Precautions Infection control guidelines from the Centers for Disease Control and Prevention stating that all body excretions, secretions, and moist membranes and tissues are potentially infectious; combines protective measures from Universal Precautions and Body Substance Isolation.

stapes One of the three bony ossicles of the ear; also called the “stirrup.”

stasis dermatitis In patients with venous insufficiency, discoloration of the skin along the ankles, which extends up to the calf.

stasis ulcer In patients with long-term venous insufficiency, ulcer formed as a result of edema or minor injury to the limb; typically occurs over the malleolus.

status epilepticus Prolonged seizures lasting more than 5 minutes or repeated seizures over the course of 30 minutes; a potential complication of all types of seizures.

steatorrhea An excessive amount of fat in the stool.

stem cell An immature, undifferentiated cell produced by the bone marrow.

stent A small tube that is placed in a tubular structure to dilate it; a wirelike device that may be used along with percutaneous transluminal angioplasty to help keep the vessel open.

stereotactic pallidotomy A surgical treatment for the patient with Parkinson disease when drugs are ineffective in symptom management. An electrode is used to create a lesion in a targeted area within the pallidum, with the goal of reducing tremor and rigidity.

stereotyping Assuming that all people in a particular culture have the group's values and beliefs or practice the group's customs.

sterilization A method of infection control in which all living organisms and bacterial spores are destroyed; used on items that invade human tissue where bacteria are not commonly found.

stimulant Any of a group of drugs that excite the cerebral cortex of the brain, producing a variety of behavioral responses and causing an increase in body activity, such as caffeine, nicotine, amphetamines, and methamphetamines.

stimulation test A type of test for pituitary function that involves injecting agents known to stimulate secretion of specific pituitary hormones and then measuring the response.

stoma The surgical creation of an opening; usually refers to an opening in the abdominal wall.

stomatitis Inflammation of the oral mucosa; characterized by painful single or multiple ulcerations that impair the protective lining of the mouth. The ulcerations are commonly referred to as “canker sores.”

strain Excessive stretching of a muscle or tendon when it is weak or unstable; sometimes referred to as “muscle pulls.”

strangulated hernia A tightly constricted hernia that compromises the blood supply to the herniated segment of the bowel as a result of pressure from the hernial ring (the band of muscle around the hernia); leads to ischemia and obstruction of the bowel loop, with necrosis of the bowel and possibly bowel perforation.

strangulated obstruction Intestinal obstruction with compromised blood flow.

stratum corneum The outermost layer of the skin.

stress test See *exercise electrocardiography*.

stress ulcers Multiple shallow erosions of the proximal stomach and occasionally the duodenum.

stress urinary incontinence Loss of urine during activities that increase intra-abdominal pressure, such as laughing, coughing, sneezing, or lifting heavy objects.

striae Reddish purple streaks on the skin, also called “stretch marks.”

stricture Narrowing.

stridor A high-pitched crowing sound caused by laryngospasm or edema above or below the glottis; heard during respiration.

stroke Former name for “brain attack”; see *brain attack*.

stroke volume The amount of blood ejected by the left ventricle during each heartbeat.

stuporous A state of being arousable only with vigorous or painful stimulation.

subarachnoid See *subarachnoid space*.

subarachnoid screw or bolt A hollow device placed into the subarachnoid space for direct measurement of intracranial pressure. It does not allow drainage of cerebrospinal fluid to treat increased pressure, but it is less invasive, which lowers the risk of infection. Compare with “intraventricular catheter.”

subarachnoid space Term for the space between the arachnoid mater and pia mater of the spinal cord; also called “subarachnoid.”

subcutaneous emphysema The presence of bubbles under the skin because of air trapping; an uncommon late complication of fracture.

subcutaneous nodule Characteristic round, movable, nontender swelling under the skin of the arm or fingers in patients with severe rheumatoid arthritis.

subcutaneous therapy Infusion therapy that is delivered under the skin when patients cannot tolerate oral medications, when intramuscular injections are too painful, or when vascular access is not available.

subdural hematoma (SDH) The collection of clotted blood that typically results from venous bleeding into the space beneath the dura and above the arachnoid.

subdural hemorrhage Venous bleeding into the space beneath the dura and above the arachnoid.

subdural space Term for the space between the dura mater and the middle layer (arachnoid).

subendocardial myocardial infarction An infarction that involves only the subendocardium, the inner layer of the cardiac muscle.

subluxation Partial joint dislocation.

submucous resection (SMR) Surgical procedure to straighten a deviated septum when chronic symptoms or discomfort occur; also called “nasoseptoplasty.”

substance abuse The overindulgence of a chemical substance and the resulting dependence that interferes with life's activities.

substance misuse The taking of chemicals for reasons other than their intended action.

substance use The taking of chemicals for pleasure without dependence.

substernally Located below the ribs.

subtotal thyroidectomy The surgical removal of part of the thyroid tissue.

sundowning In patients with Alzheimer's disease, increased confusion at night or when excessively fatigued.

superinfection Reinfection or a second infection of the same type.

supervision Guidance or direction, evaluation, and follow-up by the nurse to ensure that the task or activity is performed appropriately.

suppressed gene A particular gene that has been “turned off.”

suprapatellar area The area directly above the knee.

supratentorial Located within the cerebral hemispheres, in the area above the tentorium of the cerebellum; the tentlike fold of dura that surrounds the cerebellar hemisphere and supports the occipital lobe.

supraventricular tachycardia (SVT) A form of tachycardia that involves the rapid stimulation of atrial tissue at a rate of 100 to 280 beats/min. It is most often due to a re-entry mechanism in which one impulse circulates repeatedly throughout the atrial pathway, re-stimulating the atrial tissue at a rapid rate.

surfactant A fatty protein secreted by type II pneumocytes to reduce surface tension in the alveoli.

surgical débridement Method of debriding a wound by removing thick, adherent wound crust using a scalpel or scissors.

surveillance Term used to describe the tracking of infections by health care agencies.

susceptibility The risk of the host to infection; may be increased by the breakdown of host defenses against pathogens.

swimmer's ear See *external otitis*.

sympathectomy Surgical cutting of the sympathetic nerve branches via endoscopy through a small axillary incision.

sympathetic tone A state of partial blood vessel constriction caused when nerves from the sympathetic division of the autonomic

nervous system continuously stimulate vascular smooth muscle.

synapse The area through which impulses are transmitted to their eventual destination.

synchronous (demand) pacing mode The mode of temporary cardiac pacing in which the pacemaker's sensitivity is set to sense the patient's own beats. When the patient's intrinsic rate is above the rate set on the pulse generator, the pacemaker is inhibited from firing. When the patient's rate is below that set on the generator, the pacemaker fires electrical impulses to stimulate depolarization.

syncope Transient loss of consciousness (blackouts), most commonly caused by decreased perfusion to the brain.

syndrome of inappropriate antidiuretic hormone (SIADH) Persistent hyponatremia, hypovolemia, and inappropriately elevated urine osmolality that occurs when vasopressin (antidiuretic hormone) is secreted even when plasma osmolality is low or normal.

syndrome X See *metabolic syndrome*.

syngeneic transplant Bone marrow transplant in which stem cells are taken from the patient's own identical sibling.

synovectomy The surgical removal of synovium.

synovial joint Type of joint lined with synovium, a membrane that secretes synovial fluid for lubrication and shock absorption.

synovitis Inflammation of synovial membrane.

synthesis The process of building up.

syphilis A complex sexually transmitted disease that can become systemic and cause serious complications and even death. It is caused by the spirochete *Treponema pallidum*, which is found in the mouth, intestinal tract, and genital areas of people and animals. The infection is usually transmitted by sexual contact, but transmission can occur through close body contact and kissing.

syringe pump Pump for infusion therapy that uses a battery-powered piston to push the plunger continuously at a selected mL/hr rate; limited to small-volume continuous or intermittent infusions.

systemic Affecting the body system as a whole.

systemic lupus erythematosus (SLE) A chronic, progressive, inflammatory connective tissue disorder that can cause major body organs and systems to fail; characterized by spontaneous remissions and exacerbations.

systemic sclerosis (SSc) A chronic connective tissue disease characterized by inflammation, fibrosis, and sclerosis of the skin and vital organs; also called "scleroderma" and formerly called "progressive systemic sclerosis."

systemic vascular resistance The resistance to the flow of blood through the body's blood vessels; it increases when vessels constrict and decreases when vessels dilate.

systole The phase of the cardiac cycle that consists of the contraction and emptying of the atria and ventricles.

systolic blood pressure The amount of pressure/force generated by the left ventricle to distribute blood into the aorta with each contraction of the heart.

systolic heart failure (systolic ventricular dysfunction) Heart failure that results when the heart is unable to contract forcefully enough during systole to eject adequate amounts of blood into the circulation.

T

T wave In the electrocardiogram, the deflection that follows the ST segment and represents ventricular repolarization.

tachycardia An excessively fast heart rate; characterized as a pulse rate greater than 100 beats/min.

tachydysrhythmia An abnormal heart rhythm with a rate greater than 100 beats/min.

tachypnea An increased rate of breathing.

tactile (vocal) fremitus A vibration of the chest wall produced when the patient speaks; can be palpated on the chest wall.

tai chi A holistic movement therapy derived from a traditional Chinese martial art; has been adapted as a mind-body exercise that integrates body movements, mental concentration, muscle relaxation, and breathing to promote the flow of *qi*, or energy, in the body.

target tissues The tissues that respond specifically to a given hormone.

taut Tightly stretched.

telemetry In electrocardiography (ECG), the use of a battery-powered transmitter system for monitoring an ambulatory patient; allows freedom of movement within a certain radius without losing transmission of the ECG.

telesurgery The use of robotics to perform surgical procedures over long distances.

telomeres The "tips" of the chromosomes.

temporal field blindness A decrease in lateral peripheral vision.

temporary pacing A nonsurgical intervention for cardiac dysrhythmia that provides a timed electrical stimulus to the heart when either the impulse initiation or the intrinsic conduction system of the heart is defective.

tendon Any one of many bands of tough, fibrous tissue that attach muscles to bones.

tendon transplant Removal of a tendon from one part of the body and transplantation into the affected area to replace a ruptured tendon that cannot be repaired surgically.

tenesmus Straining, especially painful straining to defecate.

tension headache A type of headache characterized by neck and shoulder muscle tenderness and bilateral pain at the base of the skull and in the forehead; usually treated with non-opioid analgesics such as acetaminophen, aspirin, and nonsteroidal anti-inflammatory drugs.

teratogenic Tending to produce birth defects.

tetany Continuous contractions of muscle groups; hyperexcitability of nerves and muscles.

tetraplegia Another term for quadriplegia (paralysis that involves all four extremities).

thalamotomy An alternative to stereotactic pallidotomy as a surgical treatment for the patient with Parkinson disease; uses thermocoagulation of brain cells to reduce tremor. Usually only unilateral surgery is performed to benefit the side of the body most affected by the disease.

thalamus A structure within the brain; functions as the "central switchboard" for the central nervous system.

thallium scan A test that is similar to the bone scan but uses the radioisotope *thallium* and is more sensitive in diagnosing the extent of disease in patients with osteosarcoma.

The Joint Commission An organization that offers peer evaluation for accreditation every 3 years for all types of health care agencies that meet their standards. Formerly known as the "Joint Commission for Accreditation of Healthcare Organizations (JCAHO)."

therapeutic exercise A type of exercise that includes carefully planned activities designed to improve muscle strength, muscle tone, and joint range of motion and to reduce pain and improve the patient's psychological health.

thermotherapy Technique for treating benign prostatic hyperplasia that uses a variety of heat methods to destroy excess prostate tissue.

third intention healing Delayed primary closure of a wound with a high risk for infection. The wound is intentionally left open for several days until inflammation has subsided and is then closed by first intention.

thoracentesis The aspiration of pleural fluid or air from the pleural space.

threshold In evaluating hearing, the lowest level of intensity at which pure tones and speech are heard by a patient; in general, the lowest level at which a stimulus is perceived.

thrombectomy Removal of a clot (thrombus) from a blood vessel.

thrombocytopenia A reduction in the number of blood platelets below the level needed for normal coagulation, resulting in an increased tendency to bleed.

thrombophlebitis The presence of a thrombus associated with inflammation; usually occurs in the deep veins of the lower extremities.

thrombosis The formation of a blood clot (thrombus) within a blood vessel.

thrombus A blood clot believed to result from an endothelial injury, venous stasis, or hypercoagulability.

thymectomy Removal of the thymus gland.

thymoma An encapsulated tumor of the thymus gland.

thyrocalcitonin (TCT) A hormone produced and secreted by the parafollicular cells of the thyroid gland to help regulate serum calcium levels; secreted in response to excess plasma calcium.

thyroid storm (thyroid crisis) A life-threatening event that occurs in patients with uncontrolled hyperthyroidism and is usually caused by Graves' disease. Key manifestations include fever, tachycardia, and systolic hypertension.

thyrotoxicosis The condition caused by excessive amounts of thyroid hormones.

thyroxine (T₄) A hormone that is produced by the follicular cells of the thyroid gland and increases metabolism.

Tinel's sign Test that confirms a diagnosis of carpal tunnel syndrome; a positive test causes palmar paresthesias when the area of the median nerve is tapped lightly.

tinnitus A continuous ringing or noise perception in the ears.

titration Adjustment of IV fluid rate on the basis of the patient's urine output plus serum electrolyte values.

TNM (tumor, node, metastasis) System developed by the American Joint Committee on Cancer to describe the anatomic extent of cancers.

toe brachial pressure index (TBPI) Toe systolic pressure divided by brachial (arm) systolic pressure; may be performed instead of or in addition to ankle-brachial index to determine arterial perfusion in the feet and toes.

tolerance A state of adaptation in which exposure to a drug induces changes that result in a decrease in one or more of the drug's effects over time.

tomography An imaging technique that produces planes, or slices, for focus and blurs the images of other structures; different from standard x-rays, which superimpose one structure on another.

tonic Pertaining to a state of stiffening or rigidity of the muscles, particularly of the arms and legs, and immediate loss of consciousness.

tonic seizure A type of generalized seizure characterized by an abrupt increase in muscle tone, loss of consciousness, and loss of autonomic signs; lasts from 30 seconds to several minutes.

tonic-clonic seizure A type of generalized seizure consisting of a tonic phase (characterized by stiffening or rigidity of the muscles and immediate loss of consciousness); this is followed by clonic or rhythmic jerking of the extremities and lasts 2 to 5 minutes. The patient may bite his or her tongue and may become incontinent of urine or feces. Fatigue, confusion, and lethargy may last up to an hour after the seizure.

tonsillitis An inflammation and infection of the tonsils and lymphatic tissues located on each side of the throat.

tophi A collection of uric acid crystals that form hard, irregular, painless nodules on the ears, arms, and fingers of patients with gout.

torsades de pointes A type of ventricular tachycardia that is related to a prolonged QT interval.

total body surface area (TBSA) The total amount of skin surface for one person.

total hysterectomy Removal of the uterus and cervix; the procedure may be vaginal or abdominal.

total joint arthroplasty (TJA) Surgical creation of a joint, or total joint replacement; commonly performed in patients with

osteoarthritis. Also called "total joint replacement (TJR)."

total joint replacement (TJR) See *total joint arthroplasty*.

total parenteral nutrition (TPN) Provision of intensive nutritional support for an extended time; delivered to the patient through access to central veins, usually the subclavian or internal jugular veins.

total thyroidectomy The surgical removal of all of the thyroid tissue.

touch discrimination Part of the neurologic examination. The patient closes his or her eyes while the practitioner touches the patient with a finger and asks that the patient point to the area touched.

toxic and drug-induced hepatitis Liver inflammation resulting from exposure to hepatotoxins (e.g., industrial toxins, alcohol, and medications).

toxic epidermal necrolysis (TEN) A rare acute drug reaction of the skin that results in diffuse erythema and blister formation, with mucous membrane involvement and systemic toxicity.

toxic megacolon Acute enlargement of the colon along with fever, leukocytosis, and tachycardia; usually associated with ulcerative colitis.

toxic multinodular goiter Hyperthyroidism caused by multiple thyroid nodules, which may be enlarged thyroid tissues or adenomas, and a goiter that has been present for several years.

toxic shock syndrome (TSS) A severe illness caused by a toxin produced by certain strains of *Staphylococcus aureus*. It was first recognized in 1980 as related to menstruation and tampon use. It is characterized by abrupt onset of a high fever and headache, sore throat, vomiting, diarrhea, generalized rash, and hypotension. The most common manifestations are skin changes (initially a rash that resembles a severe sunburn and changes to a macular erythema similar to a drug-related rash).

toxin Protein molecule released by bacteria that affects host cell at a distant site. Continued multiplication of a pathogen is sometimes accompanied by toxin production.

trabecular Spongy bone; also called "cancellous bone."

trabeculation An abnormal thickening of the bladder wall caused by urinary retention and obstruction.

tracheostomy The (tracheal) stoma, or opening, that results from a tracheotomy.

tracheotomy The surgical incision into the trachea for the purpose of establishing an airway.

trachoma A chronic conjunctivitis caused by *Chlamydia trachomatis*.

traction The application of a pulling force to a part of the body to provide reduction, alignment, and rest.

transcellular fluid Any of the fluids in special body spaces, including cerebrospinal fluid, synovial fluid, peritoneal fluid, and pleural fluid.

transcultural nursing The area of study and practice that focuses on the care, health, and illness patterns of people with similarities and differences in their cultural beliefs, values, and practices; also, care that considers the cultural aspects of the patient.

transcutaneous electrical nerve stimulation (TENS) The use of a battery-operated device to deliver small electrical currents to the skin and underlying tissues for pain management; also called "percutaneous electrical nerve stimulation (PENS)."

transesophageal echocardiography (TEE) A form of echocardiography performed transesophageally (through the esophagus); an ultrasound transducer is placed immediately behind the heart in the esophagus or stomach to examine cardiac structure and function.

transferrin An iron-transport protein that can be measured directly or calculated as an indirect measurement of total iron-binding capacity.

transient ischemic attack (TIA) A brief attack (lasting a few minutes to less than 24 hours) of focal neurologic dysfunction caused by a brief interruption in cerebral blood flow, possibly resulting from cerebral vasospasm or transient systemic arterial hypertension. Repeated attacks may damage brain tissue; multiple attacks indicate significant increased risk for brain attack.

transmitted In genetics, the passage of a gene for a specific trait from one human generation to the next.

transmural myocardial infarction An infarction that involves all three layers of cardiac muscle.

transmyocardial laser revascularization A new surgical procedure for patients with unstable angina and inoperable coronary artery disease with areas of reversible myocardial ischemia. After a single-lung intubation, a left anterior thoracotomy is performed and the heart is visualized. A laser is used to create 20 to 24 long, narrow channels through the left ventricular muscle to the left ventricle. The channels eventually allow oxygenated blood to flow from the left ventricle during diastole to nourish the muscle.

transport maximum See *renal threshold*.

transurethral microwave therapy (TUMT) Procedure for treating benign prostatic hyperplasia using high temperatures to heat and destroy excess tissue.

transurethral needle ablation (TUNA) Procedure for treating benign prostatic hyperplasia using low radiofrequency energy to shrink the prostate.

transurethral resection of the prostate (TURP) The traditional "closed" surgical procedure for removal of the prostate. In this procedure, the surgeon inserts a resectoscope (an instrument similar to a cystoscope, but with a cutting and cauterizing loop) through the urethra. The enlarged portion of the prostate gland is then resected in small pieces.

trauma Bodily injury.

trauma activation criteria Certain injury mechanisms associated with life-threatening consequences that serve as criteria for summoning the trauma team for a rapid and coordinated resuscitation response.

trauma center Specialty care facility that provides competent and timely trauma services to patients depending on its designated level of capability.

trauma nursing Nursing specialty that encompasses the continuum of care from injury prevention and prehospital services to acute care, rehabilitation and, ultimately, community reintegration.

trauma system An organized and integrated approach to trauma care designed to ensure that all critical elements of trauma care delivery are aligned to meet the injured patient's needs.

triage In the emergency department, sorting or classifying patients into priority levels depending on illness or injury severity, with the highest acuity needs receiving the quickest evaluation and treatment.

triage officer In a hospital's emergency response plan, the person who rapidly evaluates each patient who arrives at the hospital. In a large hospital, this person is generally a physician who is assisted by triage nurses; however, a nurse may assume this role when physician resources are limited.

tricuspid valve The atrioventricular valve of the heart; separates the right atrium from the right ventricle.

tricyclic antidepressants Drugs used to treat depression.

trigeminy A type of premature complex consisting of a repetitive three-beat pattern; usually occurs as two sequential normal complexes followed by a premature complex and a pause, with the same pattern repeating itself in triplets.

trigger points In patients with fibromyalgia syndrome, tender areas that can typically be palpated to elicit pain in a predictable, reproducible pattern.

triiodothyronine (T₃) A hormone produced by the follicular cells of the thyroid gland.

tropic hormones Hormones secreted by the anterior pituitary gland that stimulate other endocrine glands.

tropical sprue A disease caused by an infectious agent that has not been identified but is thought to be bacterial. Tropical sprue results in malabsorption of fat, folic acid, and vitamin B₁₂ in later stages of the disease.

troponin A myocardial muscle protein released into the bloodstream after injury to myocardial muscle. Because it is not found in healthy patients, any rise in values indicates cardiac necrosis or acute myocardial infarction.

truss A device, usually a pad made with firm material, that is held in place over the hernia with a belt to keep the abdominal contents from protruding into the hernial sac.

tube thoracostomy A method of chest decompression performed after needle thoracostomy in which a chest tube is inserted in

the fifth intercostal space, just anterior to the midaxillary line, to promote air and fluid drainage.

tuberculosis (TB) A highly communicable disease caused by *Mycobacterium tuberculosis*. It is the most common bacterial infection worldwide.

tumescence The condition of being swollen.

tumor-induced osteomalacia See *oncogenic osteomalacia*.

tunneled central venous catheter A type of catheter used for long-term infusion therapy in which a portion of the catheter lies in a subcutaneous tunnel, separating the points where the catheter enters the vein from where it exits the skin.

turbidity Cloudiness of a solution.

turbinates Three bony projections that protrude into the nasal cavities from the walls of the internal portion of the nose.

turgor The condition of being swollen and congested; indicates the amount of skin elasticity; the normal resiliency of a pinched fold of skin.

Turner's sign Ecchymosis on either flank, which may indicate retroperitoneal bleeding into the abdominal wall.

tympanic A term that describes the high-pitched, loud, musical sound heard over an air-filled intestine; obtained upon percussion of the abdomen.

tympanic membrane The eardrum; a thick, transparent sheet of tissue that provides a barrier between the external ear and the middle ear.

type A gastritis A form of chronic gastritis associated with the presence of antibodies to parietal cells and intrinsic factor. An autoimmune pathogenesis for this type of gastritis has been proposed.

type B gastritis The most common form of chronic gastritis; caused by *Helicobacter pylori* infection; 50% of patients who have gastric ulcers have associated chronic gastritis.

tyrosine kinase inhibitors (TKIs) Drugs with the main action of inhibiting activation of tyrosine kinases. There are many different TKIs. Some are unique to the cell type; others may be present only in cancer cells that express a specific gene mutation. As a result, the different TKI drugs are effective in disrupting the growth of some cancer cell types and not others.

U

U wave In the electrocardiogram, the deflection that follows the T wave and may result from slow repolarization of ventricular Purkinje fibers. When present, it is of the same polarity as the T wave, although generally smaller. Abnormal prominence of the U wave suggests an electrolyte abnormality or other disturbance.

ulcerative colitis (UC) A chronic inflammatory process that affects the mucosal lining of the colon or rectum; one of a group of bowel diseases of unknown etiology characterized by remissions and exacerbations. It can result in

loose stools containing blood and mucus, poor absorption of vital nutrients, and thickening of the colon wall.

umbilical hernia Protrusion of the intestine at the umbilicus; can be congenital or acquired. Congenital umbilical hernias appear in infancy. Acquired umbilical hernias directly result from increased intra-abdominal pressure and are most commonly seen in obese people.

unclassified seizure One of the three broad categories of seizure disorders along with partial seizure and generalized seizure. They occur for no known reason, do not fit into the generalized or partial classifications, and account for about half of all seizure activity; also called "idiopathic seizures."

uncus The inner part of the temporal lobe of the brain that can move downward and cause pressure on the brainstem; the vital sign center.

undermining Separation of the skin layers at the wound margins from the underlying granulation tissue.

unilateral body neglect syndrome In the patient who has had a brain attack, an unawareness of the existence of the paralyzed side. For example, the patient may believe he or she is sitting up straight when actually he or she is leaning to one side. Another typical example is the patient who washes or dresses only one side of the body.

uninhibited bladder May occur with a neurologic problem that affects the cortical bladder center of the brain (frontal lobe), such as brain attack or brain injury. The patient has little sensorimotor control and cannot wait until he or she is on the commode or bedpan before voiding.

Unna boot A wound dressing constructed of gauze moistened with zinc oxide; used to promote venous return in the ambulatory patient with a stasis ulcer and to form a sterile environment for the ulcer. The boot is applied to the affected limb, from the toes to the knee, after the ulcer has been cleaned with normal saline solution and covered with an elastic wrap. The dressing hardens like a cast.

unroofing Lifting or puncturing of the outer surface of a skin lesion to obtain specimens for bacterial culture.

unstable angina Chest pain or discomfort that occurs at rest or with exertion and causes marked limitation of activity; characterized by an increase in the number of attacks and an increase in the intensity of pain. Pain may last longer than 15 minutes or may be poorly relieved by rest or nitroglycerin.

upper esophageal sphincter (UES) The ringlike band of muscle fibers at the upper end of the esophagus. When at rest, the sphincter is closed to prevent air from entering into the esophagus during respiration.

upper GI (gastrointestinal) radiographic series The radiographic visualization of the gastrointestinal tract from the oral part of the pharynx to the duodenojejunal junction; used to detect disorders of structure or function of

the esophagus (barium swallow), stomach, or duodenum.

upper motor neurons Neurons that carry motor impulses from the cerebral cortex to the cerebral nerves. Patients with spinal cord injuries involving upper motor neuron lesions experience muscle spasticity, which can lead to contractures after spinal shock has resolved.

uremia The accumulation of nitrogenous wastes in the blood (azotemia); a result of renal failure, with clinical symptoms including nausea and vomiting.

uremic frost A layer of urea crystals from evaporated sweat; may appear on the face, eyebrows, axilla, and groin in patients with advanced uremic syndrome.

uremic syndrome The systemic clinical and laboratory manifestations of end-stage kidney disease.

ureterolithiasis Formation of stones in the ureter.

ureteropelvic junction (UPJ) The narrow area in the upper third of the ureter at the point at which the renal pelvis becomes the ureter.

ureteroplasty Surgical repair of the ureter.

ureterovesical junction (UVJ) The point at which each ureter becomes narrow as it enters the bladder.

urethral meatus The opening at the endpoint of the urethra.

urethral stricture An obstruction that occurs low in the urinary tract due to decreased diameter of the urethra, causing bladder distention before hydronephrosis and hydronephrosis.

urethritis An inflammation of the urethra that causes symptoms similar to urinary tract infection.

urethroplasty Surgical treatment of the urethral stricture to remove the affected area with or without grafting to create a larger opening.

urgency The feeling that urination will occur immediately.

urgent triage In a three-tiered triage scheme, the category that includes patients who should be treated quickly but in whom an immediate threat to life does not currently exist, such as those with abdominal pain or displaced fractures or dislocations.

urinary tract infection (UTI) An infection in the normally sterile urinary system. The unobstructed and complete passage of urine from the renal and urinary systems is critical in maintaining a sterile urinary tract. When any structural abnormality is present, the risk for damage as a result of infection is greatly increased.

urolithiasis The presence of calculi (stones) in the urinary tract.

urosepsis The spread of an infection from the urinary tract to the bloodstream, resulting in systemic infection accompanied by fever, chills, hypotension, and altered mental status.

urticaria A transient vascular reaction of the skin marked by the development of wheals (hives).

uterine artery embolization Treatment for leiomyomas in which a radiologist uses a percutaneous catheter inserted through the femoral artery to inject polyvinyl alcohol pellets into the uterine artery. The resulting blockage starves the tumor of circulation, allowing it (or them) to shrink.

uterine prolapse Downward displacement of the uterus into the vagina.

uvea The middle layer of the eye, which consists of the choroid, ciliary body, and iris. The choroid has many blood vessels that supply nutrients to the retina.

uveitis Inflammation of part or all of the uvea.

V

vagal maneuver Nonsurgical management of cardiac dysrhythmias that is intended to induce vagal stimulation of the cardiac conduction system, specifically the sinoatrial and atrioventricular nodes. Vagal maneuvers may be attempted to terminate supraventricular tachydysrhythmia.

vagina The collapsible hollow tube with thin, muscular walls lined by mucous membrane and many blood vessels; extends from the vestibule to the uterus. It is the channel for the passage of menstrual flow, allows reception of the penis during intercourse, and allows passage of the fetus during a vaginal birth.

vaginectomy Surgical removal of part or all of the vagina.

vagotomy syndrome Diarrhea that develops as a result of the interruption of vagal fibers to the abdominal viscera during esophageal surgery.

validation therapy For the patient with moderate or severe Alzheimer's disease, the process of recognizing and acknowledging the patient's feelings and concerns without reinforcing an erroneous belief (e.g., if the patient is looking for his or her deceased mother).

Valsalva maneuver A form of vagal stimulation of the cardiac conduction system in which the health care provider instructs the patient to bear down as if straining to have a bowel movement.

variant (Prinzmetal's) angina A type of angina caused by coronary vasospasm (vessel spasm); usually associated with elevation of the ST segment on an electrocardiogram obtained during anginal attacks.

varicocele The surgical removal of a varicocele (a cluster of dilated veins behind and above the testis).

varicose veins Distended, protruding veins that appear darkened and tortuous; common in patients older than 30 years whose occupations require prolonged standing. As the vein wall weakens and dilates, venous pressure increases and the valves become incompetent (defective). The incompetent valves enhance the vessel dilation, and the veins become tortuous and distended.

vas deferens A firm, muscular tube that continues from the tail of each epididymis and is

a reservoir for sperm and tubular fluids. They merge with ducts from the seminal vesicle to form the ejaculatory ducts at the base of the prostate gland. Sperm from the vas deferens and secretions from the seminal vesicles are transported through the ejaculatory duct to mix with prostatic fluids in the prostatic urethra. Also called "ductus deferens."

vascular access device A catheter; a plastic tube placed in a blood vessel to deliver fluids and medications.

vasculitis Blood vessel inflammation.

vasoconstriction Decrease in diameter of blood vessels.

vaso-occlusive event (VOE) A blood vessel obstruction caused by masses of sickled RBCs.

vasopressin Secretion of the posterior pituitary gland, also known as "antidiuretic hormone" or "ADH."

vasospasm A sudden and transient constriction of a blood vessel.

Vaughn-Williams classification System used to categorize antidysrhythmic agents according to their effects on the action potential of cardiac cells.

vegan A vegetarian diet pattern in which only foods of plant origin are eaten.

venous beading A complication of diabetes; the abnormal appearance of retinal veins in which areas of swelling and constriction along a segment of vein resemble links of sausage. Such bleeding occurs in areas of retinal ischemia and is a predictor of proliferative diabetic retinopathy.

venous duplex ultrasonography A noninvasive test using ultrasonic waves; the preferred diagnostic test for deep vein thrombosis.

venous insufficiency Alteration of venous efficiency by thrombosis or defective valves; caused by prolonged venous hypertension, which stretches the veins and damages the valves, resulting in further venous hypertension, edema and, eventually, venous stasis ulcers, swelling, and cellulitis.

venous thromboembolism (VTE) A term that refers to both deep vein thrombosis and pulmonary embolism; obstruction by a thrombus.

ventilation assistance Process or devices to help the patient breathe easily (e.g., mechanical ventilation assistance).

ventral hernia Protrusion of the intestine at the site of a previous surgical incision resulting from inadequate healing. Most often caused by postoperative wound infections, inadequate nutrition, and obesity.

ventricular asystole The complete absence of any ventricular rhythm. There are no electrical impulses in the ventricles and therefore no ventricular depolarization, no QRS complex, no contraction, no cardiac output, and no pulse, respirations, or blood pressure. The patient is in full cardiac arrest.

ventricular fibrillation (VF) A cardiac dysrhythmia that results from electrical chaos in the ventricles; impulses from many irritable foci fire in a totally disorganized manner so

that ventricular contraction cannot occur; there is no cardiac output or pulse and therefore no cerebral, myocardial, or systemic perfusion. This rhythm is rapidly fatal if not successfully terminated within 3 to 5 minutes.

ventricular gallop An abnormal third heart sound that arises from vibrations of the valves and supporting structures and is produced during the rapid passive filling phase of ventricular diastole when blood flows from the atrium to a noncompliant ventricle. In patients older than 35 years, it is an early sign of heart failure or ventricular septal defect.

ventricular remodeling (1) Progressive myocyte (myocardial cell) contractile dysfunction over time; results from activation of the renin-angiotensin system caused by reduced blood flow to the kidneys, a common occurrence in low-output states; (2) after a myocardial infarction, permanent changes in the size and shape of the left ventricle due to scar tissue; such remodeling may decrease left ventricular function, cause heart failure, and increase morbidity and mortality.

ventricular tachycardia (VT) An abnormal heart rhythm that occurs with repetitive firing of an irritable ventricular ectopic focus, usually at a rate of 140 to 180 beats/min or more.

ventriculomyomectomy The surgical excision of a portion of the hypertrophied ventricular septum to create a widened outflow tract in patients with obstructive hypertrophic cardiomyopathy.

ventriculostomy The surgical placement of an intraventricular catheter to drain cerebrospinal fluid in patients with increased intracranial pressure and rapidly deteriorating neurologic function.

vertebroplasty A minimally invasive surgery for managing vertebral fractures in patients with osteoporosis. Bone cement is injected directly into the fracture site to provide immediate pain relief.

vertigo A sense of spinning movement that may result from diseases of the inner ear.

vesicant Chemical that causes tissue damage on direct contact.

vesicant medication A drug that causes tissue damage when extravasated.

vesicle In health care, a small bladder or blister.

vestibule A longitudinal area between the labia minora, the clitoris, and the vagina that contains Bartholin glands and the openings of the urethra, Skene's glands (paraurethral glands), and vagina.

viral hepatitis Inflammation of the liver that results from an infection caused by one of five major categories of viruses (hepatitis A, B, C, D, or E). Viral hepatitis is the most common type and can be either acute or chronic.

viral load testing Test that measures the presence of human immune deficiency virus genetic material (ribonucleic acid) or other viral proteins in the patient's blood.

viral meningitis A type of meningitis that often occurs after viral illnesses such as

measles, herpes simplex, coxsackievirus, and echovirus; it is marked by inflammation over the cerebral cortex, white matter, and meninges. The formation of exudate (common in bacterial meningitis) does not occur, and no organisms are obtained from the cerebrospinal fluid. Also called "aseptic meningitis."

Virchow's triad The occurrence of stasis of blood flow, endothelial injury, or hypercoagulability; often associated with thrombus formation.

viremia The presence of viruses in the blood.

virilization The presence of male secondary sex characteristics.

virtual colonoscopy A noninvasive alternative to the colonoscopy procedure. A scanner is used to view the colon.

virulence A term used to describe the frequency with which a pathogen causes disease (degree of communicability) and its ability to invade and damage a host. Virulence can also indicate the severity of the disease; often used as a synonym for pathogenicity.

visceral proteins Proteins such as albumin that circulate in the bloodstream and may be produced by the liver.

viscous Of thick consistency.

vitaligo An abnormality of the skin characterized by patchy areas of pigment loss with increased pigmentation at the edges. It is seen with primary hypofunction of the adrenal glands and is due to autoimmune destruction of melanocytes in the skin.

vitrectomy The surgical removal of the vitreous.

vitreous body The clear, thick gel that fills the vitreous chamber of the eye (the space between the lens and the retina). This gel transmits light and shapes the eye.

vocational counselor A member of the rehabilitative health care team who assists the patient with job placement, training, or further education.

volutrauma Damage to the lung by excess volume delivered to one lung over the other.

volvulus Obstruction of the bowel caused by twisting of the bowel.

vulva The external female genitalia; extends from the mons pubis to the anal opening.

vulvar self-examination (VSE) A method for self-examination of the external female genitalia for early detection of diseases of the vulva.

vulvectomy Surgical removal of the vulva, labia majora, labia minora, and, possibly, the clitoris.

vulvovaginitis Inflammation of the lower genital tract resulting from a disturbance of the balance of hormones and flora in the vagina and vulva.

W

warm antibody anemia A form of immunohemolytic anemia (in which the immune system attacks a person's own red blood cells for unknown reasons) that occurs with immunoglobulin G antibody excess and may be

triggered by drugs, chemicals, or other autoimmune problems.

warm phase A phase lasting 2 to 3 weeks after peripheral nerve trauma resulting in complete denervation; the extremity is warm, and the skin appears flushed or rosy. The warm phase is gradually superseded by a cold phase.

water brash Reflex salivary hypersecretion that occurs in response to reflux in the patient with gastroesophageal reflux disease.

wean The process of going from ventilatory dependence to spontaneous breathing.

"wearing off" phenomenon Loss of response over time to a medication.

wedge resection Removal of small, localized areas of disease.

Wernicke's aphasia See *receptive aphasia*.

Wernicke's area An important speech area of the cerebrum. It is located in the temporal lobe and plays a significant role in higher-level brain function. It enables the processing of words into coherent thought and recognition of the idea behind written or printed words (language).

Whipple procedure (radical pancreaticoduodenectomy) A surgical treatment for cancer of the head of the pancreas. The procedure entails removal of the proximal head of the pancreas, the duodenum, a portion of the jejunum, the stomach (partial or total gastrectomy), and the gallbladder, with anastomosis of the pancreatic duct (pancreaticojejunostomy), the common bile duct (choledochojejunostomy), and the stomach (gastrojejunostomy) to the jejunum.

white matter In the spinal cord, myelinated axons that surround the gray matter (neuron cell bodies).

Williams position A position in which the patient lies in the semi-Fowler's position and flexes the knees to relax the muscles of the lower back and relieve pressure on the spinal nerve root. This is typically more comfortable and therapeutic for the patient with low back pain.

withdrawal syndrome Symptoms that occur when a patient who is physically dependent on opioids abruptly stops using them. Slowly tapering (weaning) the drug dosage lessens or alleviates the physical withdrawal symptoms in a patient who is opioid dependent. Also called "abstinence syndrome."

withdrawing or withholding life-sustaining therapy (WWLST) The withdrawal or withholding of one or more therapies that might prolong the life of a person who cannot be cured by the therapy; the withdrawal of therapy does not directly cause death. Formerly called "passive euthanasia."

work-related musculoskeletal disorders (MSDs) Disorders caused by heavy lifting and dependent transfers by staff members.

X

xenograft Tissue transplanted (grafted) from another species; for example, a heart valve transplanted from a pig to a human.

xeroradiography A diagnostic x-ray technique in which images are produced electrically rather than chemically, permitting lower exposure times and radiation energies than those of ordinary x-rays. The images exhibit “edge contrast,” which is useful for identifying minute calcifications in the breast.

xerosis Abnormally dry skin.

xerostomia Abnormal dryness of the mouth caused by a severe reduction in the flow of saliva.

x-ray Radiation that is generated by machine.

Z

Zollinger-Ellison syndrome (ZES) The occurrence of upper gastrointestinal tract

ulceration, increased gastric acid secretion, and the presence of a non-beta cell islet tumor of the pancreas, called a “gastrinoma.” Affected people may have more than one gastrinoma.

changes associated with aging, 860
chronic kidney disease and, 1549, 1551-1552, 1551b
drugs impairing function of, 862t
hemostasis and, 858-859, 859f, 860t
manifestations of liver dysfunction and, 1297f
manifestations of nutrient deficiencies and, 1341t

Hematoma
bone healing and, 1145f
intravenous therapy-related, 228t-229t

Hematopoiesis, 1107
cancer and, 409

Hematopoietic stem cell transplantation
in aplastic anemia, 878
conditioning regimen in, 886-887, 887f
engraftment in, 887
evidence-based practice in, 888b
in leukemia, 884-889
in myelodysplastic syndromes, 880
prevention of complications in, 887-889
in sickle cell disease, 875

Hematuria
in acute glomerulonephritis, 1528
after kidney biopsy, 1487
after pancreas transplantation, 1444
assessment of, 863
in benign prostatic hyperplasia, 1630
in cervical cancer, 1625
in polycystic kidney disease, 1521
in prostate cancer, 1637
in urinary tract infection, 1493
in urolithiasis, 1508-1509

Hemianopsia, 1011, 1012f

Hemiarthroplasty, 331

Hemilaryngectomy, 591t

Hemiparesis, 1009

Hemiplegia, 1009

Hemoconcentration, 176
in burn, 516
in diabetes mellitus, 1412-1413

Hemodialysis
in acute kidney injury, 1545, 1545f
in chronic kidney disease, 1558-1564
anticoagulation in, 1560
complications of, 1563-1564, 1563b
dialysis settings in, 1558-1559
dialyzable and vasoactive drugs after, 1563t
nursing care in, 1562, 1563b
older adult and, 1563b
patient selection for, 1558
peritoneal dialysis *versus*, 1558t
post-dialysis care and, 1562-1563
procedure in, 1559-1560, 1559f-1560f
vascular access in, 1560-1562
dietary restrictions in, 1555t
in hypothermia rewarming, 149
patient and family education in, 1572

Hemodialysis catheter, 220

Hemodialysis circuit, 1559f

Hemodialysis machine, 1560f

Hemodilution, 179

Hemodynamic monitoring
in abdominal trauma, 1259
in cardiovascular assessment, 708-710, 708b, 709f

Hemoglobin
as buffer, 200
in burn assessment, 524b
in cardiovascular assessment, 703
in colorectal cancer, 1247
in diverticular disease, 1285
in heart failure, 749-750
in hypovolemic shock, 817b
in kidney disease, 1542b
laboratory profile of, 865b
in malnutrition, 1342
oxygen-hemoglobin dissociation curve and, 547-548, 547f
in peptic ulcer disease, 1229
perioperative assessment of, 249b-250b
pulse oximetry and, 556
red blood cell production of, 857

Hemoglobin A, 870

Hemoglobin A_{1c}, 1370, 1413, 1419, 1419b, 1420t

Hemoglobin electrophoresis, 864, 865b

Hemoglobin S, 870-871

Hemolytic anemia
in brown recluse spider bite, 143
in glucose-6-phosphate dehydrogenase deficiency, 876
in sickle cell disease, 871

Hemolytic jaundice, 1295t

Hemolytic transfusion reaction, 901

Hemophilia, 896, 896b, 897t

Hemoptysis
in laryngeal trauma, 586
in pulmonary embolism, 664
respiratory assessment and, 551

Hemorrhage
brain herniation and, 1022-1023
conjunctival, 1056
in diverticular disease, 1284-1285
in epistaxis, 582-583, 582b, 582f
of esophageal varices, 1294, 1302-1303
in gastritis, 1222
in hemodialysis vascular access, 1562t
in hemothorax, 684
in peptic ulcer disease, 1226-1227, 1226f

in amputation, 1164
in coronary artery bypass graft, 848b
in glaucoma surgery, 1067
in kidney biopsy, 1487
in laryngectomy, 592
in nephrectomy, 1533
in pancreatic cancer, 1332
in total hip arthroplasty, 325t, 327
prevention during chemotherapy, 422b
in pulmonary embolism, 668, 668b-669b
risk in leukemia, 889, 892b
in spinal cord injury, 969
in stress ulcer, 1226
during thyroid surgery, 1399
tracheostomy-related, 572
in ulcerative colitis and Crohn's disease, 1273t
vitreous, 1067-1068

Hemorrhagic stroke, 1005f, 1006-1007, 1006t

Hemorrhoidectomy, 1261

Hemorrhoids, 1260-1262, 1261f

Hemostasis, 858-859, 859f, 860t

Hemothorax, 231t, 684

Hemovac drain, 292f, 295

HEPA respirator, 657, 657f

Heparin
after total hip arthroplasty, 327
for anticoagulation in hemodialysis, 1560, 1564
for atrial fibrillation, 727
interaction with sulfonyleurea agents, 1428t
for percutaneous transluminal coronary angioplasty, 844
for pulmonary embolism, 665, 665b-666b

Heparin-induced thrombocytopenia, 800, 896-897

Hepatic abscess, 1288-1289, 1310

Hepatic arterial infusion, 1311

Hepatic artery embolization, 1311

Hepatic disorders, 1293-1314
cirrhosis in, 1293-1296
ascites and esophageal varices in, 1294, 1300b
biliary obstruction in, 1294-1295
bleeding episodes in, 1302-1303
community-based care in, 1303-1305
concept map for, 1299f-1301f
etiology and genetic risk in, 1296, 1296t
health care resources for, 1304
hepatic encephalopathy in, 1294-1295, 1295t
hepatorenal syndrome in, 1295-1296
history in, 1296
home care management in, 1303-1304
imaging assessment in, 1299
incidence and prevalence of, 1296
jaundice in, 1294-1295, 1295t, 1300b
laboratory assessment in, 1298-1299, 1299t
management of excess fluid volume in, 1299-1302, 1300b
pathophysiology of, 1294-1296
physical assessment in, 1296-1298, 1297f
portal hypertension in, 1294
psychosocial assessment in, 1298

CONCEPT OVERVIEW: MOBILITY, SENSATION, AND COGNITION

UNIT X PROBLEMS OF MOBILITY, SENSATION, AND COGNITION: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE NERVOUS SYSTEM

- 43 Assessment of the Nervous System, 905
- 44 Care of Patients with Problems of the Central Nervous System: The Brain, 927
- 45 Care of Patients with Problems of the Central Nervous System: The Spinal Cord, 959
- 46 Care of Patients with Problems of the Peripheral Nervous System, 986
- 47 Care of Critically Ill Patients with Neurologic Problems, 1004

UNIT XI PROBLEMS OF SENSATION: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE SENSORY SYSTEM

- 48 Assessment of the Eye and Vision, 1039
- 49 Care of Patients with Eye and Vision Problems, 1052
- 50 Assessment of the Ear and Hearing, 1077
- 51 Care of Patients with Ear and Hearing Problems, 1088

UNIT XII PROBLEMS OF MOBILITY: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE MUSCULOSKELETAL SYSTEM

- 52 Assessment of the Musculoskeletal System, 1106
- 53 Care of Patients with Musculoskeletal Problems, 1119
- 54 Care of Patients with Musculoskeletal Trauma, 1143

CONCEPT OVERVIEW: NUTRITION, METABOLISM, AND BOWEL ELIMINATION

UNIT XIII PROBLEMS OF DIGESTION, NUTRITION, AND ELIMINATION: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE GASTROINTESTINAL SYSTEM

- 55 Assessment of the Gastrointestinal System, 1177
- 56 Care of Patients with Oral Cavity Problems, 1192
- 57 Care of Patients with Esophageal Problems, 1203
- 58 Care of Patients with Stomach Disorders, 1220
- 59 Care of Patients with Noninflammatory Intestinal Disorders, 1240
- 60 Care of Patients with Inflammatory Intestinal Disorders, 1266
- 61 Care of Patients with Liver Problems, 1293

- 62 Care of Patients with Problems of the Biliary System and Pancreas, 1315
- 63 Care of Patients with Malnutrition and Obesity, 1335

UNIT XIV PROBLEMS OF REGULATION AND METABOLISM: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE ENDOCRINE SYSTEM

- 64 Assessment of the Endocrine System, 1358
- 65 Care of Patients with Pituitary and Adrenal Gland Problems, 1371
- 66 Care of Patients with Problems of the Thyroid and Parathyroid Glands, 1393
- 67 Care of Patients with Diabetes Mellitus, 1410

CONCEPT OVERVIEW: URINARY ELIMINATION

UNIT XV PROBLEMS OF EXCRETION: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE RENAL/URINARY SYSTEM

- 68 Assessment of the Renal/Urinary System, 1465
- 69 Care of Patients with Urinary Problems, 1489
- 70 Care of Patients with Renal Disorders, 1518
- 71 Care of Patients with Acute Kidney Injury and Chronic Kidney Disease, 1537

CONCEPT OVERVIEW: SEXUALITY

UNIT XVI PROBLEMS OF REPRODUCTION: MANAGEMENT OF PATIENTS WITH PROBLEMS OF THE REPRODUCTIVE SYSTEM

- 72 Assessment of the Reproductive System, 1575
- 73 Care of Patients with Breast Disorders, 1588
- 74 Care of Patients with Gynecologic Problems, 1611
- 75 Care of Male Patients with Reproductive Problems, 1629
- 76 Care of Patients with Sexually Transmitted Disease, 1652

Bibliography, 1668

Appendixes

- A Do-Not-Use Abbreviations and Symbols, 1720
- B Communication Quick Reference for Spanish-Speaking Patients, 1723

Glossary, 1727
